## VOLKMANN'S ISCHEMIC CONTRACTURE

ASSOCIATED WITH SUPRACONDYLAR FRACTURE  
OF HUMERUS

HENRY W MEYERDING, M D  
ROCHESTER, MINN

The flexion deformity of the wrist and fingers resulting from contraction and fibrosis of the flexor muscles of the forearm, which is known as Volkmann's ischemic contracture, is of especial interest (fig 1). Affecting children and occurring as a complication of fractures of the lower end of the humerus, it results in permanent partial or total disability when once it is established despite the most expert surgical and physical treatment.

It is of interest to note that in the articles and reports of cases published since the original report of Volkmann in 1869 no author has claimed a certain method of cure. While there has been some difference of opinion, in the past, as to the factors involved in the production of the contracture, we at the Mayo Clinic believe that the etiology is now readily understood and that the means of prevention are available. To those who will carefully observe the symptoms and take proper measures to control circulation in the extremity immediately following injury, Volkmann's contracture will not present the embarrassing medicolegal question as to responsibility.

The extensiveness of the primary injury and the time interval between trauma and consultation are of the utmost importance, irrespective of the treatment given, and these are the factors which fix responsibility and which should be appreciated and emphasized when the physician is charged in the courts of law with negligence and malpractice. Patients with these unsightly extremities make an unusual appeal to the jury, yet the fact that Volkmann's ischemic contracture can occur even when no treatment has been given must be emphasized and understood by the public and the profession.

There should be no misunderstanding of the merits of conservative methods of stretching, as advocated by the late Sir Robert Jones, or of operative treatment, for surgery is resorted to only when conscientious and prolonged treatment has failed to correct the deformity. It is only through the use of these conservative stretching and surgical methods that benefit will be obtained in cases of Volkmann's contracture of long standing. Without physical therapy little can be accomplished. In every case of ischemic contracture, whether operation is performed or not, it is my opinion that physical therapy is the greatest aid in recovery of a useful extremity.

At the Mayo Clinic a series of 162 cases of Volkmann's ischemic contracture have been encountered, and I have selected for the present study sixty-nine cases in which supracondylar fracture was present (table 1). The histories and physical and laboratory examinations were reviewed and an attempt was made to judge the benefits of the treatment given, and, most important, of those measures which, if instituted in time, might have resulted in prevention. I was impressed with the variation in degree of damage done (table 2), type of treatment or lack of it given (table 3), and difficulties encountered in obtaining results. Most of our patients came long distances, long after disability had occurred (table 4), and were unable to remain a satisfactory period of time. In spite of these handicaps the patients were encouraged and what was considered the maximal treatment was rendered in the time available. The family physician and relatives were given every assistance in the after-care, with encouraging results.

Every experienced physician knows that muscles which are seriously involved in cases of Volkmann's contracture mean permanent disability and that the best the profession has to offer is improvement in function and appearance. We claim no certain cure, we present our experience and the results obtained in cases of fracture of the lower end of the humerus complicated by ischemic contracture and the means of prevention and treatment.

The factors leading in cases of fracture of the lower end of the humerus to the production of Volkmann's ischemic contracture are as follows. The force which breaks off the lower fragment carries the condyles backward and strips the periosteum away from the posterior surface of the proximal fragment, this space promptly filling with blood. The lower end of the proximal fragment is carried forward and downward, piercing the periosteum and forcing its way against the soft tissues, blood vessels and nerves become compressed and hemorrhage infiltrates the antecubital spaces and, if severe, as from a ruptured artery, forces its way into the forearm. Nerves may be severed and paralysis may be noted before there has been time for an ischemic condition to develop. Transportation or undue roughness or lack of skill in handling the fractured extremity may aggravate the damage and increase intrinsic pressure. Muscle pull holds the overlapping bones in malposition, further impairing circulation in the forearm.

The extent of injury up to this time depends on the type of fracture and local damage to soft tissues. Left alone, the result may be malunion, with a fairly good functional result in the forearm and some limitation of motion in the elbow. Should arterial hemorrhage be unchecked, venous flow is interfered with by the development of a subfascial hematoma, distention, tenderness and induration of the antecubital space and pain, cyanosis and loss of pulse and numbness take place.

Infiltration into the forearm is confined by the interosseous membrane, radius, ulna and the inelastic aponeurosis of the large flexor muscles. The arm then becomes cold and blue or purplish, the pulse is absent, blebs appear, intense pain occurs, and, unless intrinsic pressure is relieved, contracture takes place. In a matter of hours, not days or weeks, the damage to the muscle fibers has been done, owing to unavoidable circumstances, the patient may not have seen a physician or had any treatment whatever. The patient expects the fracture to be reduced, and the inexperienced

practitioner (fig 2 a and b). These cases included those in which the fractures had been reduced and the patients had apparently left the offices of their physicians in comfort, circulation having been satisfactory, but in which on the patient's next visit an unlooked for contracture was discovered. It is unfortunate that the general practitioner, who must of necessity travel considerable distances daily, is unable to see his patients as often as he would like and is forced to depend on unskilled aid in protecting himself. Ideal hospital and nursing care are, however, not always available. When

practitioner who is confronted with induration of the antecubital space may attempt reduction and fixation in flexion, using bandages, splints or casts, if he is wise, he will devote his efforts to relieving the intrinsic

pressure. Patients are seen at a somewhat later stage, swelling may have become marked and reduction is attended with difficulty. Holding the fracture in acute flexion cuts off circulation and the recumbent position should be insisted on and the arm should be suspended for a few days until reduction can more safely be accomplished. An airplane splint is excellent for ambulatory patients. Why so many patients should be permitted to be up and about with arms swollen and cyanotic and hanging at their sides is difficult to understand.

A third group of patients is seen after the antecubital space is distended and tender and the pulse is faint, the skin has then become bluish red and pain is unbearable, opiates having often been freely administered. If splints, bandages, adhesive tape or casts have been applied, they should be removed and the arm should be elevated on pillows, with the elbow extended beyond a right angle. Warm, but not hot, moist dressings should then be applied. If within the next hour the swelling increases and the pulse is absent, the relatives must be warned as to the seriousness of the situation and preparation should be made to operate. Intrinsic pressure has in such cases become sufficient to

pressure and will disregard the fracture. In such cases he would do well to call some one in consultation lest he receive blame though wholly undeserved, for having produced the disability through his treatment.

Uncomplicated supracondylar fractures treated immediately by accurate reduction and retention in flexion give excellent results. Repeated observations of the color of the hand and of pulsations should be made lest an unrecognized hemorrhage appear and impair circulation. The position of the fragments should be checked to make sure displacement has not occurred, anteroposterior and lateral roentgenograms should be taken immediately after reduction and at various intervals thereafter.

In a previous paper I pointed out that malunion occurred in 40 per cent of cases of fracture associated with ischemic contracture and I believe that the displacement occurred in many instances during attempts at relieving pain and swelling by releasing the retentive

block the venous flow, but the stronger walled artery still permits a little blood to be forced into the arm. In the cases of older patients with impaired blood vessels and feeble hearts gangrene is possible, but in children the stage is set for ischemic contracture.

A fourth group of patients is encountered after several manipulations have been performed and considerable time has intervened since the fracture. The arm is then distended to such an extent as to demand immediate relief through surgical measures. There is no time to be lost, as degenerative changes may not be complete and viable tissue may yet be saved. It is at times impossible to judge accurately as to the amount of damage done to the nerves and blood vessels for the circulation is no longer active and, with its loss, the nerve supply becomes numbed and the finer distinctions

cutaneously by means of a special knife. The fracture may be reduced and internal fixation used by means of bone screws or Kirschner wire, which may be passed up through the condyles into the proximal fragment. The entire arm is then enclosed in a large, moist alcohol and boric acid dressing and is suspended in abduction. The physician who has mastered the preventive mea-

of sensation and motion are lost. Relatives should be advised and operation resorted to in the hope of preserving the function of the forearm, treatment of the fracture being of secondary importance. Skeletal traction, by means of a Kirschner wire through the olecranon, is an excellent method of correcting malposition of the fragments and should not in certain cases be overlooked as a useful aid, either as a preliminary to exploration of the hematoma or after careful operative inspection of the brachial artery.

Fig. 2—*a* Volkmann's ischemic contracture. The patient was a boy aged 4 years. He had suffered a supracondylar fracture of the right humerus. The arm had been kept in splints for two weeks when flexion deformity and pressure sores in the antecubital region had developed. Then the arm had been splinted again. The ischemic contracture was of grade 3 and there was a scar in the antecubital region resulting from pressure. *b* evidence of malunion of the supracondylar fracture of the humerus and claw hand.

and median nerve. Free incision over the hematoma and through the deep fascia liberates muscle tissue and blood that have been under tension. An incision mesial to the biceps permits the bicipital fascia to be divided close to the tendon and the artery, vein and nerve can readily be inspected. Complete rupture of the brachial artery has been observed as well as partial or complete severance of the nerve. The deep fascia over the forearm may require division and this may be done sub-

#### CONSERVATIVE TREATMENT OF VOLKMANN'S ISCHEMIC CONTRACTURE

Volkmann's ischemic contracture may occur in a few hours, and the earlier treatment is begun the better the results will be. The consultant is often called after the contracture has been present for some time, and he finds the wrist flexed, the metacarpophalangeal joints extended, and the phalanges acutely flexed. Motion at the elbow is often restricted and the hand is held in pronation, supination may be impossible and numbness of the forearm exists. As the damage to the soft tissues may be benefited by release of intrinsic

pressure, a consideration of the methods previously described should be given. No time should be lost in attempting gradual extension of the involved muscles, and the stretching method of the late Sir Robert Jones is generally recognized as excellent.

While the wrist is acutely flexed, it will be found that the fingers can be extended. Metallic splints are then fitted to each finger to maintain the corrected position

Fig. 4.—Banjo splint used to obtain extension of fingers and wrist

The patient now attempts systematically to extend the metacarpophalangeal joints, which are contracted. In a few days the joints stretch sufficiently to allow the application of longer splints, which extend to the wrist. After the wrist is exercised for a few days the splint is extended to the elbow, and among such splints can be used those which maintain extension of the hand. Thus the contracture is gradually and painlessly overcome.

I have found many splints in use but I prefer the simple and inexpensive wooden tongue depressors found in every physician's office (fig. 3). With these padded and held by strips of adhesive tape, the principles of Jones may be carried out until stretching of the wrist requires longer splints, which are usually made of a thin piece of boxwood. The use of rubber bands to pull the extended hand toward the longer splint is useful in extending the wrist. The banjo splint, used with rubber bands fastened to adhesive tape on the fingers, permits the fingers to be exercised at all times and is most efficient; it is inexpensive, can be made in a few minutes, and permits the patient to be cared for at home (fig. 4).

Care must be taken to gain the confidence of these children, and after a short time they will become interested and will cooperate exceedingly well. Thus the first few treatments may consist of heat and whirlpool baths combined with light massage. The splints soon may be adjusted and worn during the intervals between treatments. Active motion is performed willingly, and as confidence is gained active motion may be supported by gentle passive motion and electrical stimulation. We

at the clinic rely principally on heat and massage as aids to gradual stretching and do not believe that painful, passive motion or forceful manipulation under anesthesia is advisable.

The next stage in the treatment of Volkmann's ischemic contracture is that in which several months have elapsed since fracture, during which time treatment has been inadequate. The pain and swelling are gone and the hand is sensitive to cold and has the typical claw-like position, motion is limited. Usually the hand is held in pronation and there is limitation of motion in the elbow. Ulceration and scars from pressure of splints and bandages are not infrequent. Paralysis from primary injury or secondary to scar formation may involve one or more of the main nerve trunks. The radial pulse may be absent, and the arm and hand have lost the cyanotic appearance and are white. Attempts to straighten the fingers with the wrist extended bring out the tight flexor tendons and the hard atrophied flexor muscles, the finger nails cut into the hand of the examiner. The extensor group of muscles are, on the other hand, preserved or only slightly involved. There may be atrophy of bone and myositis ossificans, and roentgenograms may disclose malposition of the fracture, requiring correction. All forms of treatment now prove less satisfactory, and prolonged and adequate conservative treatment is best. First the Jones, or banjo splint, method of extension, combined with physical therapy, should be tried. When this has failed, the next stage is reached and surgery may now render the contracture more responsive to conservative treatment.

Fig. 5.—The operation. a line of incision on palmaris longus tendon. b vaginal fascia exposed. c left incisions which make possible stretching of tendon and right tendon stretched. d tendons in process of being stretched by use of hemostat.

In the third stage a group of deformities of longer duration is encountered, years often having passed with the contracture persisting in spite of treatment. Marked contracture, atrophy of bone, scars, contracted capsules, nerve degeneration and impaired circulation and a ropelike musculature challenge the most expert surgical care. The surgeon must now realize that no matter what type of operation is performed or how

skilfully it is done, he cannot bring about complete cure, when all other means have failed he is the only recourse, and he plans the operation in the hope of bringing about an improved cosmetic result and some return of function. If the flexor muscles are entirely fibrous the prognosis is poor. The surgeon should also remember that without careful postoperative care and prolonged and intelligent physical therapy he can accomplish little.

Through lengthening of tendons the surgeon is able to obtain extension of the fingers and wrist, the extent and benefit of this procedure depending on the damage done (fig 5). A longitudinal incision parallel to the palmaris longus muscle is made and the vaginal fascia is divided, exposing the muscle and tendon. By retracting the fascia one exposes the superficial group of muscles, and the tendons are lengthened by two oblique sections, 2.5 cm apart, three fourths of the distance across the tendons, stretched by means of forceps passed underneath. The usual muscles lengthened are the palmaris longus, flexor carpi radialis, flexor pollicis longus, and flexor digitorum profundus. In some instances the surgeon will find the median nerve bound down in a fibrous scar and neurolysis will be advisable, also the tendency to supination in the more resistant cases may be benefited by section of the pronator quadratus or the pronator teres.

I have observed a considerable difference in the amount of fibrous scar tissue and fixation of the structures about the wrist. In some cases it is possible to leave the tendons in their sheaths during operation and a minimum of retraction, scarring and adhesions results. When lengthening of the flexor pollicis longus and flexor digitorum profundus is performed, considerably more trauma is likely to result, binding the entire mass in scar tissue. With care this operation can be carried out with distinct satisfaction to the patient (fig 6), it allows correction of the deformity and improved function.

Neurolysis is beneficial especially when pressure sores are obvious and scars cause contracture and fixation of the nerve. The condition found at operation frequently leads the surgeon to conclude that the entire ischemic contracture is the result of injury to and fixation and degeneration of nerves. I feel that the changes in the nerves are usually secondary to the ischemia unless a primary injury or rupture occurs at the time of accident or manipulation. I have seen complete rupture of the median nerve following supracondylar fracture and ischemic contracture. In this series of cases the radial nerve was most commonly injured.

Resection of bone is resorted to in long standing cases of contracture in which the tendons are extremely short and all attempts at conservative treatment have failed. A bone graft may be used to bridge and maintain the wrist in extension. The stretching of nerves and blood vessels after years of contracture, during which time the bone has grown and the tendons have remained as they were, is not practical. I cannot agree with some who condemn this operative procedure of removal of bone. There is a group of older patients with long standing deformity in which resection of the carpal bones or radius and ulna give excellent cosmetic results and a measure of functional benefit.

Lowering of the common origin of the flexors at the epicondyle is an operation which partially releases contracture and is used in combination with gradual stretching. It may be performed at the same time the median and ulnar nerves are examined.

When the proximal end of the humerus projects forward in malunion, preventing flexion of the elbow or excessive callus formation or an ossifying hematoma exists, excision of the bony mass may be of benefit. Often there is contracture of the capsule of the elbow that will require capsulotomy. The biceps tendon may require lengthening as a result of involvement of the muscle from ischemia or long contracture. Even arthroplasty of the elbow would be preferable should the foregoing measures fail to permit movement and the function of the arm be not too seriously damaged. Sympathectomy has not as yet had a fair trial, but in one case it seemed to be of some aid.

Several patients have been encountered who had such extensive and long standing deformity and disability as to warrant amputation, in order to rid them of a useless and unsightly deformity.

Fig 6—Volkman's ischemic contracture with malunion. The patient was a youth aged 19 years. Five years before he had sustained a supracondylar fracture and splints had been applied. When these had been removed scars from sloughing and deformity and stiffness of the arm, elbow, wrist and fingers had been disclosed. The patient was operated on and has reported that function is good. Scars can be seen on the arm and over the fifth metacarpal.

The prognosis depends on many factors: the age of the patient, the type of bandages, splints and casts used and whether they have caused pressure sores and scars, the extent of hemorrhage, and whether good union or malunion was obtained, whether infection was present or there was damage to blood vessels or nerves, the presence of an ossifying hematoma, and degree of contracture and extent of fibrosis of muscle.

#### SUMMARY

Volkman's ischemic contracture is most frequently associated with supracondylar fractures treated by acute flexion. In the presence of swelling and hemorrhage, acute flexion tends to impair circulation by increasing pressure in the antecubital space, even though the fracture is reduced.

Reduction of the fracture may be deferred several days, the treatment being directed to the care of the soft parts in order to preserve function. Elevation of the arm hastens the relief of swelling in recumbent treatment, abduction on an airplane type of splint in the ambulatory treatment. Drainage of large hematomas may be indicated. Reduction and internal fixa-

tion of the fracture following removal of blood clots is feasible and is a useful aid in preventing impaired circulation

Prevention is possible in many instances, provided the patient is seen in time and the utmost care is used to combat circulatory damage

Hemophilia also may cause Volkmann's ischemic contracture

Conservative methods of treatment, such as the stretching method as advised by Sir Robert Jones, constant stretching with the banjo splint, and physical therapy, give the best results. Severe deformities of long standing require in addition surgical intervention

Intrinsic or extrinsic pressure from various causes cuts off the venous flow while permitting some arterial flow, hemorrhage, with the formation of blood clots, infiltration, edema, acute flexion, malposition of fragments, and pressure of bandages, splints and casts are some further factors concerned in impairing circulation

In obtaining the history special attention should be paid to the type of injury, the length of time before treatment, and evidence of injury to blood vessels or nerves. A record of the previous treatment, together with roentgenograms taken before and after reduction, should be available before the consultant assumes responsibility

Volkmann's ischemic contracture may result from injury or hemophilia even when treatment has not been given

## THE MISUSE OF TANNIC ACID

FREDERIC TAYLOR, MD

INDIANAPOLIS

At the present time the tannic acid treatment of burns is in more general use than any other. It has attained its great popularity through its success in extremely severe burns in which the life of the patient is at stake and when wound dressings form an important part of the problem

Because of this acceptance in the more severe burns, tannic acid is being used quite extensively in the less severe burns. It is a common sight to see the skin of the ambulatory clinic patient blackened by a tanning agent. Numerous ointments containing tannic acid or other protein coagulating material are on the market. Fortunately these have not become generally adopted. Nevertheless they are frequently used, as is tannic acid in the treatment of simple "second degree" burns

The argument in this procedure is that since tannic acid is generally thought to be quite the approved method of treating severe burns it must likewise be the treatment of choice in less severe burns. In the present article the fallacy of this line of reasoning will be pointed out and some of the tissue changes occurring in the burned and subsequently tanned skin will be analyzed

With the injury of the skin by heat, a varying thickness of the epithelium is killed. When this involves only the superficial layers, regeneration takes place quite rapidly from the remaining germinal layer. If the germinal layer also is destroyed, regeneration takes place from the depths of hair follicles and sebaceous glands where the epithelium is still viable. Under favorable conditions this new growth of epithelium proliferates over adjacent granulation tissue, thus

eventually covering the entire surface. From a theoretical standpoint, remnants of sweat glands should be able to undergo the same proliferation. However, in the skin sections of burned tissue thus far studied, this source of a regenerating epithelium seems to be negligible. If the burn has destroyed the epithelium of the hair follicle and sebaceous gland there is of course no possible source of regeneration except about the periphery, where destruction was less severe. This type of "third degree" burn forms a small minority of burns encountered

### ACTION OF TANNIC ACID ON SKIN

If the usual 5 per cent tannic acid solution or any other protein coagulating material is applied to uninjured skin, the outer layers are tanned or "fixed." If this tanning process is continued with sufficient intensity, the "prickle cell" layer and even the germinal layer may become "fixed" and therefore killed. During the usual tannic acid treatment the germinal layer of normal skin is not tanned by the process. It is well protected by the heavy cornified layer of the human skin. However, tanning may often extend well down into the "prickle cell" layer of the normal skin

Quite a different condition exists following the use of tannic acid on injured or burned skin. The dead epithelium is of course "tanned" rather rapidly. If the process stopped at this point, the treatment could certainly be termed ideal. Unfortunately with the usual treatment the tannic acid continues to penetrate and "tans" the underlying viable epithelial cells, the very cells that might have taken such an active part in the regeneration of the surface epithelium

It is the common belief that tannic acid precipitates the protein of only the dead or injured tissue. This seems evident, since the uninjured epithelium does not become blackened by the repeated application of tannic acid. The reason for this apparent failure to become tanned is the protective action of the cornified epithelial layer. This strongly resists the acid and prevents it from damaging the underlying delicate germinal layer. However, once this cornified layer is destroyed or broken the tannic acid readily reaches the germinal layer or the outer portions of the hair follicles. Here it "tans" these actively growing cells quite easily and rapidly. Thus the treatment destroys many of those very cells from which one expects active regeneration to occur

This precipitation of the germinal layer by tannic acid is known to all who have studied sections from such tissue. In figure 1 is shown a section taken from the margin of a burn three days old. It occurred in a child whose clothes became ignited while at play. The treatment consisted of the usual spray method of applying 5 per cent tannic acid solution. It is noted that the viable epithelium stops abruptly where the tannic acid coagulum begins. There are no living epithelial cells in or beneath this coagulum. It is of course possible that the burn ended just as abruptly as is indicated in the photomicrograph and that the coagulum included only the dead epithelium. This, however, seems highly improbable, especially since practically all similar sections studied present the same abrupt termination of living epithelium. It seems more probable then that the cornified layers adjacent to the living epithelium in figure 1 were injured by the burn, thus allowing the tannic acid to penetrate to the germinal cells and incorporate these in the coagulum

The ability of tannic acid solution to "tan" live epithelium is easy to demonstrate experimentally. Figure 2 illustrates the skin of a rabbit that has been painted with 5 per cent tannic acid twenty-five times during a six hour period. It will be noted that the rabbit (or most experimental animals for that matter) has practically no protective cornified skin layer. Therefore the tanning solution may act on the germinal epithelium with little interference. In the photomicrograph the entire surface epithelium has been tanned and thus killed. The tanning process has extended down along the hair follicle to a point indicated by the arrow. Beneath the arrow is noted the usual heavy band of inflammatory cell infiltration. In the illustration most of the epithelial cell nuclei are plainly visible and give the impression that their cells are still alive. This is due to the fact that they have been thoroughly "fixed" by the tanning solution and the section has been removed just twenty-four hours after the tannic acid was first applied.

It may be argued that if the underlying viable epithelium is coagulated by the treatment too much tannic acid has been used. Who can say just how much to apply in a given burn, or, for that matter, who can say on first inspection of a recent burn just how deep the burn has penetrated? What epithelial islands have been killed? What islands may survive unless they are immediately coagulated by tannic acid?

No one would consider treating the donor site of a split skin graft with tannic acid. Yet this situation is quite comparable with the usual burn in which regeneration must also take place from the remaining living epithelial cells of the hair follicles.

It would seem wiser then in the treatment of the great majority of burns not to institute any therapy that might destroy surviving epithelial cells. As previously mentioned, first inspection of a burn, except in

solution of sodium hypochlorite or ointments be instituted until it can be determined just which epithelium will survive and which will die. It is fully admitted that this procedure creates a definite problem of dressing the wound. These are painful and dirty and greatly increase the nursing care required. This care does,

Fig 2—Normal skin of rabbit tanned and removed eighteen hours later. The epithelial cells are tanned and thus killed over the entire surface and down into the hair follicle to the point indicated by the arrow. Regeneration in this case would have to start from the very base of the follicle. The usual band of inflammatory cell infiltration is noted beneath the coagulated surface (just under the arrow).

however, allow the uninjured epithelium to proliferate at maximal speed and to cover the denuded area in the shortest length of time.

It is not within the scope of this discussion to consider those extremely severe cases for which the original Davidson tannic acid treatment was suggested.<sup>1</sup> That, or at least a form of coagulation therapy, has come to stay, principally because of the greater ease with which these patients can be handled. It should, however, be pointed out that the greatly lowered mortality which has been reported in the use of tannic acid in burns is no doubt due to two factors entirely apart from the coagulative solution itself. These are (1) an increased interest on the part of the hospital staff treating cases of burns and (2) a full appreciation of the resultant shock and the replacement of lost fluids of the body.

Coan<sup>2</sup> has recently suggested the use of ferric chloride as a coagulant. This would seem to offer much the same objections found in tannic acid. Of the numerous coagulants that have been advocated, the 1 per cent gentian violet suggested by Aldrich<sup>3</sup> is the least harmful to the regenerating epithelial cells. In the present study it was found that gentian violet will destroy germinal epithelium, but to a lesser extent, and will not penetrate or cause the severe local reaction encountered with tannic acid.

Fig 1—Margin of a burn three days old which has been treated with tannic acid. The coagulum has been torn in sectioning. Note that the epithelium ends abruptly and that no viable germinal cells are found beneath the coagulation zone.

rare cases will not reveal which tissue will live if given favorable opportunity and which will die. Therefore it is suggested that any coagulating material be withheld from all burns except the more extreme cases in which the life of the patient is at stake. It is further suggested that bland dressings of saline solution, dilute

## SUMMARY

1 The tannic acid treatment of burns was originally advocated for use in severe, extreme cases. It is now frequently used in milder "second degree" burns.

2 The action of tannic acid applied to a burned area in which viable islands of the germinative epithelial cells still survive is not limited to the dead tissue. Many of the epithelial cells that might take part in the repair of the denuded area are also "tanned" by the treatment. Repair is thus delayed.

3 It is suggested that coagulation treatment of burns be reserved for the most severe types and that bland wet dressings and ointments be used on the great majority of "second degree" burns.

## CLINICAL MONGOLISM IN COLORED RACES

## WITH REPORT OF A CASE OF NEGRO MONGOLISM

ARNOLD GESELL, MD

Director of the Clinic of Child Development Yale University  
School of Medicine

NEW HAVEN, CONN

As early as 1843 Sequin described a mongolian type of mental defect in France and later Lombroso of Italy recognized the condition in his account of Mattinette Colombo. It remained for J. Langdon Down in 1866 to delineate a clinical picture of mongolism. As late as 1903 very little had been written on the subject except in Great Britain. Muir<sup>1</sup> mentions two German and five American references and states that mongolism seems to be confined to the Caucasian race.

This point of view was generally accepted until 1922, when Tumpeer<sup>2</sup> and Demuth<sup>3</sup> reported two cases in Chinese children. Interest in the racial aspects of mongolism received an impetus in 1924, when Crookshank<sup>4</sup> denied the possibility of mongolism occurring in the Negro, although reports of three cases had been published prior to 1924. Bullard<sup>5</sup> had reported one case in 1911 and von Hofe<sup>6</sup> two in 1922.

## SURVEY OF THE LITERATURE

I have made a survey of the literature and find that since 1924 a total of twenty-eight cases of Negro mongolism have been reported in America. In the present paper I am reporting an additional case, bringing the grand total of cases in the medical literature to thirty-two. These cases are all listed in table 1. The present survey also revealed five Chinese cases, more than sixty Japanese, one Hindu and one West Indian case.

It was once doubted whether mongolism occurs in the Semitic race. The literature, however, now reports cases in Jews from Asia Minor, Germany, France, England, Poland and Galicia. In the United States it has been found in Austrian, Russian, Rumanian and American Jews.

In a series of 2,090 admissions to the Fountain Mental Hospital (England), Dr. Brushfield<sup>7</sup> reported

- 1 Muir J. An Analysis of Twenty Six Cases of Mongolism. Arch Pediat 20: 161-169, 1903.
- 2 Tumpeer H. Mongolian Idiocy in a Chinese Boy. J A M A 79: 14-16 (July 1) 1922.

177 mongolians. For 151 of these, case histories were obtained and twenty-four, or one in 65, proved to be British born Jews, a rather high proportion.

The number of countries or nationalities in which mongolism is now known to occur is at least twenty-three, as follows: Australia, Austria, Bermuda, China, Holland, England, France, Germany, Greece, Italy,

## AN INSTITUTIONAL AND SCHOOL CENSUS OF NEGRO MONGOLIANS

My interest in the racial aspects of mongolism has grown out of the experience in our own clinic. Over a period of twenty-three years we have diagnosed 107 cases of mongolism: fifty-six girls and fifty-one boys. In the same period we have examined 215 Negro children referred for developmental diagnosis. Only one of these presented mongolism. Inquiry showed that in

a similar period there has not been a single case of Negro mongolism in the state school for the feeble-minded. Connecticut has a colored population of over 29,000. This accordingly suggested a low rate of incidence.

In order to secure further statistical indications of the frequency of mongolism among Negroes, we made a

Fig 1—Comparison of clinical and racial mongolism. Above, mongolism in a Chinese infant aged 7 months; below, a normal Chinese infant aged 3½ months. (After Demuth.)

nation-wide canvass by letters addressed to state officials and other persons who might furnish information.<sup>8</sup> The following questions with slight variations were included in the letters of inquiry:

- 1 Present white population enrolled in your institution?
- 2 Number of white mongolians in this population?
- 3 Present colored population enrolled in your institution?
- 4 Number of colored mongolians in this population?
- 5 Number of colored mongolians admitted in previous years?

TABLE 2—Mongolism as Observed in Institutions

<b>Reported in literature</b>							
Inclusion of present case						32	
<b>Total</b>				2335		115	

A total of fifty-six institutions, three large general metropolitan hospitals and four public school special class systems reported mongolians, either white or Negro. The results are tabulated in table 2.

<sup>8</sup> I wish to acknowledge the cooperativeness of the numerous persons who furnished information. I am particularly indebted to the following for making available statistical data from their records: Dr. Neil A. Davton, director of statistics and research, Department of Mental Diseases of Massachusetts; Miss Elizabeth A. Walsh, acting director of the Board of Education of the City of New York; Miss Normal E. Cutts, supervisor of the Department of Exceptional Children of New Haven, Conn.; Harvard Medical School Children's Hospital, Boston; Johns Hopkins Hospital, Baltimore; Presbyterian Hospital, New York.

This canvass, including the thirty-two cases assembled from the literature, yields a total of 115 Negro mongolians identified by clinics, schools and institutions. The number is far from complete, but it is sufficiently large to controvert (once again!) Crookshank's positive assertion that mongolism does not occur among Negroes. Since a race is being dealt with which has only recently been transplanted into a new, civilized environment, and since mongolism possibly has an endocrine basis, it would be interesting to know whether these figures represent an increasing trend. But the requisite data for a judgment are not available.

These figures cover forty-two states in the Union and are sufficiently comprehensive to be indicative. From the Southern states excepting Texas, which supplied no data, only forty-two mongolians were reported. Two Negro institutions with a population of 3,389 reported no mongolian whatever. Even if it is assumed that less than one tenth of the feeble-minded population is institutionalized, this figure suggests a low incidence for Negro mongolism. In the Northern states, where institutional provisions for the colored population are probably more abundant, the trends seem similar. Connecticut is a fair example. In round numbers it has a white population of 1,500,000 and a colored population of 30,000, a ratio of 50 white to 1 black. The State Institution for the Feeble-minded cares for 1,230 white and forty colored persons, among whom there are forty-two white mongolians. In the whole history of the institution, extending over twenty years, no colored mongolian has been committed. As already mentioned, the Yale Clinic of Child Development, over a similar

Fig 2—Clinical mongolism in a Japanese infant aged 18 months. (After Yamashita.)

period of years, has received only one colored mongolian among a total intake of 107 mongolians. If the racial proportions in the general population were statistically maintained, our clinic should have had two colored mongolians on its panel, and the state institution at least one.

Dr. Dunlap<sup>9</sup> of Dallas, Texas, likewise finds that no case of Negro mongolism has been encountered in five

<sup>9</sup> Dunlap, J. E. Mongoloid Idiocy in a Negro Infant. *J. Pediat.* 2: 615 (May) 1933.

years in the Baylor University outpatient service, even though the colored attendance is double that of the whites, among whom three or four mongolians appear each year. It is such apparent disparities which build up the impression that mongolism in the Negro is extremely rare.

The available figures for the country as a whole make a similar impression. In terms of our canvass the number of ascertained (certified) white mongolians is 0.0016 per cent of the total continental white population of the United States. On the other hand, the number of ascertained colored mongolians is 0.00069 per cent of the entire colored population. If gratuitously one took these figures at a face value, white mongolism would appear to be two and a half times more frequent than Negro mongolism.

It should be noted here that of the 115 Negro mongolians listed forty-seven were reported by institutions, sixty-one by hospitals and physicians, and seven by directors of special classes. This would suggest that hospital populations now afford a more accurate indication of the frequency of mongolism among Negroes. The reported cases were invariably brought to the hospitals for respiratory and other ailments, and the diagnosis of mongolism was incidentally made.

Fig 3—Two institutional Negro mongolians. I J, aged 10 years and 8 months, mental level 3 years. W D, aged 16 years, mental level 2 years. (Courtesy of R. L. Dixon.)

Figures can be cited to show that the incidence for the black and the white race is nearly equal. For example, in sixteen institutions caring for 1,607 colored patients thirty, or 1.8 per cent, are mongolians. The

same sixteen institutions care also for 30,487 white patients, 843, or 2.7 per cent, of whom are mongolians. This is a close approximation, particularly when one recalls that the mongolian is often so benign and manageable that he can be readily cared for at home.

The figures for Massachusetts are important because of the extensive institutional provisions of this state. Out of a total population of 4,250,000, Negroes number

Fig 4—Clinical mongolism in a Negro girl (author's case). N M, aged 4 years and 4 months, developmental level between 12 and 24 weeks.

52,000, a ratio of approximately 80 to 1. The cases in resident population at the three state schools total to 4,933, of whom seventy-six are black and thirty-seven mulatto. The number of white mongolians is 203, the number of black mongolians, two. This roughly satisfies the ratio of 80 to 1.

Still more indicative are the statistics for public school special classes which enroll both white and black subnormal pupils. Out of a total enrolment of 14,376 white pupils, thirty-nine are mongolians. Out of a total of 1,848 colored pupils, six are mongolians. These percentages are significantly close, namely, 0.27 and 0.32. Distorting selective factors are probably least strong in determining the racial composition of public school classes for defective children. We have in this parallelism a strong basis for believing that mongolism is not significantly infrequent in the colored race.

#### RACIAL AND CLINICAL STIGMAS

The racial theory of the origin of clinical mongolism is weakened by the differences between a normal Chinese child and a developmental mongolian. When the two were compared side by side, Demuth found that in the mongolian child the skull is very decidedly brachycephalic, the forehead precipitous. It rises directly upward from the eyes, while in the normal child it recedes in the form of a sphere. The occipital head line lies parallel to the forehead. The flat saddle nose scarcely reaches the level of the forehead, its end is broad, the nostrils extend upward. The eyes are not only (normally) slit or almond shaped but very oblique, and the eyeballs converge. Epicanthus is characteristic.

For a comparison of racial and clinical features of mongolism the reader is referred to the instructive photographs reproduced from Demuth's report (fig 1).

Tumpey likewise found that the clinical features were not masked by the racial. The clinical mongolian presents a moon-shaped face without prominent cheek bones, and his eyes are more slitlike than those of normal siblings. Indeed, for developmental reasons the eyeballs of the clinical mongolian are set in oblique orbits and are not horizontally aligned as in the yellow race.

The single case from India, described by Amir Chand,<sup>10</sup> presents such well defined features that the patient was nicknamed "Chinaman" by his neighbors. Mongolism is reported to be extremely rare in India. Crookshank asserted that it never occurs among the Dravidian population of India.

For further sidelights on the susceptibility to mongolism among Negroes I have examined the literature bearing on the distinctive biologic characteristics of the African race. Bakwin<sup>11</sup> gives a useful bibliography on this subject in connection with his study of the Negro infant. He finds rickets, tetany, convulsions and stillbirths much more frequent among Negro infants. On the other hand, deaths from birth injury and congenital malformations are much more frequent among white infants. Negroes have a shorter trunk length

Although such differences are suggestive of a biologic disparity between the two races, they do not conclusively show that the white race is more liable to clinical mongolism.

I have discovered only three cases of cretinism in the Negro. If this condition is in fact so exceptional<sup>15</sup> it is a point of interest, because certain writers hold that there may be a fundamental relationship between cretinism and clinical mongolism. Collier<sup>16</sup> has reported one instance of these two conditions occurring in the same family. Tumpeo found in his case of mongolian idiocy in a Chinese boy that the basal metabolism rate was not significantly lowered and that restlessness rather than lethargy characterized the boy's behavior. Occasionally, however, it is reported that thyroid therapy has a beneficial effect on the early physical if not

Fig. 5.—N M showing characteristic behavior as recorded by the cinema. A, spontaneous supine behavior, prolonged hand regard. Note the broad gap between the great toe and the adjacent toe. B, mouth reaching for rattle presented in the median line. C, demonstration of hypermotility of joints. D, head retraction without ocular fixation. E, mouthing of cube without inspection. F, protusion of tongue and imperfect sitting balance.

and a smaller vital capacity than whites. In external body size and conformation and in the anatomy and physiology of his internal organs the Negro is different from the white. Bean<sup>12</sup> states that the Negro has a smaller temporal brain lobe and a smaller spleen. A greater incidence of mental deficiency has been asserted.<sup>13</sup> Dayton's<sup>14</sup> statistics for the institutional population of feeble-minded, however, show that 109 out of 4,816 whites presented developmental anomalies, while not one of 113 blacks and mulattoes was so classified.

The proportion of total mortality attributable to lesions of the nervous system, the kidneys and associated excretory organs, and the endocrine system is in each case smaller in Negroes than in whites.

mental development of the mongolian. This again is suggestive of a relationship between cretinism and mongolism.

#### CLINICAL MONGOLISM IN A NEGRO CHILD (AUTHOR'S CASE)

N M was referred to the Clinic of Child Development when she was 13 months of age. The parents are presumably full blooded. Two older siblings are normal. The mother worked throughout her pregnancy, but the child was born at full term with a birth weight of 7½ pounds (3,402 Gm.) and was nursed for three months. The home is clean, but the father has religious beliefs which have interfered at times with the child's adequate nourishment.

At the age of 13 months the patient weighed 16½ pounds (75 Kg.) and was 29 inches (73⅓ cm.) in height. She presented a behavior picture of low grade defect. She was flaccid and generally relaxed. She could not sit up, even with ordinary support. She preferred the supine position, rolling constantly to the left side. Her major activity in addition to this

15. The author is interested in securing more data on this interesting question and would appreciate any information which readers may bring to his attention.

16. Collier, W. T. Cretinism and Mongolism in the Same Family. *Brit M J* 2: 1044-1045 (Dec. 20) 1930.

rolling was a recurrent transfix regarding of the hand. She could not reach for a rattle. She held it, when inserted in the palm, momentarily and without inspection. But her own hand she repeatedly inspected for prolonged periods whenever it came within a favorable ocular distance. She made no social response either to her examiner or to her mother. She vocalized in a monotonous, shrill, inarticulate manner. Her behavior patterns were atypical as well as retarded and were in general at or below a 12 weeks level of maturity.

The patient was again examined three years later, at the age of 4 years and 4 months. She proved to have made little developmental progress in the interval. Her behavior remained atypical and had scarcely advanced to a 20 weeks maturity level.

Her physical and behavior characteristics are outlined in table 3. They are further suggested in the accompanying reproductions of photographs (figs. 4, 5 and 6), which were derived from a cinema record made when the child was placed in a clinical crib and subjected to

Fig. 6—Plantar dermatograph showing coarseness of skin creases

the various test situations of a developmental examination. Her behavior capacities may be summed up as follows:

#### Postural Behavior—

She still prefers to lie on her back. She can sit (with marked lumbar kyphosis) for short periods, leaning on her hands. She rolls from back to side and sometimes to prone. She cannot herself attain a sitting position.

#### Perceptual Behavior—

She can be made to attend to a 1-inch cube on a table top. She does not regard a pellet. She frequently and prolongedly regards her own hand.

#### Prehensory Behavior—

She closes in on a rattle when lying down and holds it prolongedly. She seizes a cube with crude palmar grasp when sitting.

#### Adaptive Behavior—

She manipulates a rattle without inspecting it.

She senses loss of a rattle but does not pursue it when it drops.

**Social Behavior—**She shows very meager social responsiveness. She attends more to the examiner's hand than to his face. She articulates a few inflected syllables.

#### SUMMARY

1 This paper attempts to throw light on the frequency of clinical mongolism in the colored races, with special reference to Negroes. The data that are presented include a survey of the literature, the results of a nation-wide canvass of institutions and schools, and the report of a new case.

2 In the illustrations the clinical stigmas are delineated to differentiate between clinical and racial characteristics.

3 Clinical mongolism in Negroes is more frequent than is commonly supposed. One hundred and fifteen cases were identified. Statistics for Massachusetts and for metropolitan public school systems, when analyzed,

TABLE 3—Outline of Characteristics of N. M., Aged 4 Years and 4 Months

Age 4 years 4 months	
Sex Female	
Race Negro	
Anthropometric Measurements	
Height	Vertex 92.5 cm
	Suprasternal 71.6 cm
	Symphysium 40.6 cm
Diameters	Biauricular 19.7 cm
	Mesocephalic 16.2 cm
	Iliac crest 13.4 cm
Girth	Chest 30.4 cm
Weight	13.07 kg
Head	
Length	15.8 cm
Breadth	12.3 cm
Girth	46.0 cm
Intracranial distance	34 mm
Anterior fontanel	open and depressed admitting finger tip
Forehead	well developed
Nose	extremely flat and broad at base
	Nasolabial junction confluent poorly defined
Eyes	obliquely set in oblique orbits
	Eyelashes long and upturned
	Internal strabismus
Ears	malformed adherent helix folded over
Tongue	tip papillate
Lower lip	full and fissured
Hard palate	vaulted
Teeth	irregular upper especially so right lateral incisor deviates outward
Thyroid	palpable
Spine	lumbar kyphosis
Abdomen	protuberant umbilicus protuberant
Skin	clear soft and redundant
Hands and feet	fingers tapered nails pink and well developed
	Great toe widely separated palmar and solar skin coarsely creased
Postural behavior	Atypical at 24 weeks level
Perceptual behavior	Near 20 weeks level
Prehension	In part at 24 weeks level
Adaptive behavior	12-20 weeks level
Social behavior	Markedly defective below 12 weeks level*

\* These developmental ratings are based on norms as specified in Gesell, Arnold, and Thompson, *Helen: Infant Behavior Its Genesis and Growth* New York: McGraw-Hill Book Company, 1934, and Gesell, Arnold, and others, *An Atlas of Infant Behavior: A Systematic Delineation of the Forms and Early Growth of Human Behavior Patterns* New Haven: Conn. Yale University Press, 1934. Illustrated by 3,200 action photographs in two volumes.

suggest that clinical mongolism occurs with almost equal frequency in black and white populations.

4 The distinctive biologic characteristics of the African race do not necessarily indicate greater immunity to clinical mongolism among Negroes, although congenital malformations are much more frequent among white infants.

5 In the author's case of clinical mongolism in a Negro child, behavior status was determined by a developmental examination. A tabular summary lists the thirty-one additional cases reported in the literature.

14 Davenport Avenue

**Minerals in Lean Meat—**When allowance is made for the difference in the moisture content, lean meat is closely comparable to whole-grain cereals in its content of the better known mineral elements. Both cereals and meat are fairly rich in phosphorus and iron but poor in calcium. Therefore, while the addition of meats, fish and poultry to a dietary based chiefly on cereals makes up for the deficiency of certain amino acids in the proteins of the grains it does not supply the calcium so inadequately furnished by grain products. The glandular organs are relatively richer than the muscles in iron, phosphorus, copper and manganese but they too are low in calcium. Salt water fish and shellfish are among the richest sources of iodine in the dietary.—Sherman, H. C. *Food and Health*, New York, Macmillan Company, 1934.

THE ADDITIVE EFFECT OF CALCIUM  
AND DIGITALIS

A WARNING, WITH A REPORT OF TWO DEATHS

J O BOWER, MD

AND

H A K MENGLE, MD

PHILADELPHIA

The specific therapeutic action of most drugs is generally well established and their action may be predicted with a fair degree of certainty. The use of drugs in combination has also led to recognition of the fact that certain drugs enhance the action of others—a synergistic effect. That certain drugs counteract the action of others, i e., physiologic antagonism, is also common

Calcium gluconate was introduced in 1927 and is available for intramuscular or intravenous use in a 10 per cent aqueous solution. It was presented as an improvement over the chloride and the lactate. It is not so irritating as calcium chloride and is much more effective than calcium lactate. The anion, gluconic acid, is easily destroyed by the body, being converted into dextrose. It requires very large amounts to cause toxic symptoms and because of its apparent harmlessness it is recommended by the manufacturers for oral, intramuscular and intravenous use. They point out that the effect following the intravenous injection is almost instantaneous, a hypercalcemia which lasts for some hours, after which the blood calcium gradually returns to its normal level. They list no contraindications. The following cases are reported because of our conviction

Fig 1—Calcium gluconate after injection of digalen

knowledge. However, the administration of one drug may produce a sensitization of the tissues, which so modifies the functional response of the tissues that a second drug exerts an effect diametrically opposed to its customary and expected action. This alteration of the functional activity of the cells may be produced by physical-chemical forces, by disease or by drugs.<sup>1</sup>

that there are very definite contraindications to the use of calcium intravenously.

CASE 1—A white woman, aged 32, admitted in our service Jan 2, 1935, with a history of several attacks of upper abdominal pain accompanied by nausea and vomiting, had a general history and physical examination typical of cholecystitis and cholelithiasis. The cardiac history was negative except for

Fig 2—Calcium chloride after injection of digalen

There are many examples of drugs exhibiting this reversal of action under varying conditions.

Calcium may produce a varying cardiac response, depending on existing circumstances. Its action is affected not only by the state of the cardiac musculature but by the earlier administration of other drugs. Furthermore, when calcium is employed beforehand, the action of other drugs may be modified.

slight edema of the ankles, subsiding over night. The heart was normal by physical examination. The blood pressure was 120 systolic, 70 diastolic. The bromosulfalein test showed 35 per cent dye retention at the end of two hours. Cholecystectomy was performed January 3 under ether anesthesia. A single mulberry stone with hemorrhagic bile was found in the gallbladder. Two days after operation the pulse was 100, the blood pressure was 90 systolic, 50 diastolic, and extrasystoles were noted. Digalen, 15 minims (1 cc) every four hours, was administered and the following day the pulse rate dropped to 90 and the blood pressure rose to 120 systolic, 58 diastolic. Six days after operation the patient's abdomen was normal, she

From the Department of Surgical Research Temple University School of Medicine and the Philadelphia General Hospital.  
1. Hanzlik, P. J. The Basis of Allergic Phenomena. J. A. M. A. 52: 2001-2007 (June 21) 1924.

was passing gas, there was no distention and she was taking fluids by mouth without nausea. Her pulse, however, continued rapid and weak at a rate of 120. A medical consultant was called with reference to the tachycardia, as the lungs and abdomen were apparently normal. He suggested calcium intravenously, as he felt that 'the tachycardia was probably due to toxic irritation of the accelerator mechanism through sympathetic involvement.' Up to this point the patient had received approximately 250 minims (15 cc) of digalen over a period of six days. The last dose preceded the administration of calcium by at least twenty-four hours. The patient was given 10 cc

of twenty hours. October 22 he developed a fine tremor of both hands, which was diagnosed as beginning tetany. Ten cc of 10 per cent calcium chloride was injected intravenously, followed by the administration of physiologic solution of sodium chloride by means of the same needle, 50 cc of the latter fluid had been given when the patient suddenly developed cardiac collapse. One cc of epinephrine was given immediately still with the same needle. After one or two minutes the heart action could no longer be discerned, so 15 cc of epinephrine was injected intracardially without avail. Following this the respirator was applied with no response.

Fig. 3—Calcium gluconate after digalen produced death as in figures 1 and 2. Before the administration of the second dose of calcium the digalen shows little additional effect.

of a 10 per cent calcium gluconate solution through a 26 gage hypodermic needle into the right antecubital vein. We used the gluconate because we considered it less irritating than the chloride. The injection was stopped after 5 cc was given and the patient was engaged in conversation. After the injection was completed, she was asked if she felt all right. She replied that she did. About two minutes later her pupils dilated and she had a generalized convulsion with only slight muscular fibrillations. The heart sounds could not be elicited and the patient stopped breathing. In spite of artificial respiration and epinephrine given both intravenously and into the heart, the patient gave only a few inspiratory gasps and the heart sounds never returned. Autopsy revealed nothing definite as to the cause of death. Microscopic examination of the liver was negative. The heart muscle was flabby but not markedly so.

#### COMMENT

Several causative factors at once suggest themselves in case 1: liver damage, autonomic instability, speed shock, and the synergistic action of calcium and digitalis. Although the liver at operation seemed soft and bled easily, at autopsy it was very flabby, and the liver function test showed 30 per cent retention yet the pathologist's report hardly justifies classifying this case as a death due to hepatic insufficiency.

Autonomic instability is a vague term and while there are undoubtedly instances in which death is due to some powerful stimulation of the autonomic nervous system, there is too great a tendency to ascribe catastrophes to some such vague generalization. Every one is to some

Fig. 4—Digalen preceded by calcium chloride. Note that more pronounced effects are produced when calcium follows the administration of digalen.

Immediately following this catastrophe, we learned from the surgical resident that a similar case had occurred in the service of the late Dr. Harvey Righter.

**CASE 2**—A R., a white man, aged 55, admitted to the hospital Sept. 11, 1933, had fractures of both femurs. Roentgen examination showed decalcification of the bones of the pelvis, the upper thirds of both femurs and the lower two lumbar vertebrae and decalcification of the bones of the head. The blood pressure was 130 systolic, 80 diastolic. There was general arteriosclerosis. The heart was apparently normal. There was clubbing of the terminal phalanges. A diagnosis of multiple myeloma or hyperparathyroidism was made. October 20, complete extirpation of the right lobe of the thyroid with the external capsule and possible parathyroid was performed. No parathyroid tumor was found. The patient returned from the operating room in fair condition. He received 1,470 cc of fluid, including 140 minims (85 cc) of digalen over a period

degree either vagotonic or sympathicotonic, and even in cases of recognized pronounced instability some additional stimulus is required to produce a fatality.

Physiologists and pharmacologists have long known that excess of calcium ions slows the heart rate and that large doses will stop the heart in systole. Macleod<sup>2</sup> states that perfused hearts may be kept beating for long periods of time in oxygenated Ringer's solution but that if the potassium ions are removed the heart stops in systole.

In 1931 Arnold Lieberman<sup>3</sup> reported the digitalis-like effects of calcium gluconate and cautioned against

<sup>2</sup> Macleod, J. J. R. *Textbook of Physiology*, ed. 7, St. Louis: C. V. Mosby Company, 1935.  
<sup>3</sup> Lieberman, A. L. *Comparative Studies on Calcium Gluconate and Other Calcium Salts*. J. A. M. A. 97: 15-17 (July 4) 1931.

its intravenous use. In 1933 he<sup>4</sup> studied the effect of calcium gluconate and scillaren administered together. He chose scillaren because its action is practically identical with that of digitalis and because it is quite stable and uniform in its action. He found that if one-half the lethal dose of scillaren was injected first, it required approximately one-half the calculated amount of calcium gluconate to kill the animal. On the other hand, if one-half the lethal dose of calcium gluconate was administered first, it required slightly more than the calculated amount of scillaren (106 per cent) to kill the animal. He prefers to call this an "additive" rather than a "unilateral synergistic" effect, and he believes that it is due to two substances of similar action acting at dissimilar speeds. The action of calcium (intravenously) is almost instantaneous, while scillaren requires from twenty to thirty minutes to exert its full effect. In all his experiments the injections were given at the rate of 4 cc per minute.

Lieberman also studied the rate of administration and found that if calcium gluconate was given very slowly, 0.5 cc per minute, from nine to twelve times as much could be administered before the blood pressure was disturbed as when the drug was injected at the rate of 1 cc per second.

Lloyd<sup>5</sup> in 1928 issued a warning against the intravenous use of calcium. This investigator injected 4 cc of 10 per cent calcium chloride into his own antecubital vein, while connected to an electrocardiograph; he became cyanotic, dyspneic and then lost consciousness for five minutes. It required epinephrine intracardially, precordial massage and artificial respiration to resuscitate him. During this time there were no oscillations recorded on the electrocardiograph. He states, somewhat dryly, that there were no ill after-effects.

#### EXPERIMENTAL WORK

In an endeavor to confirm these results, we studied the effects of large but sublethal doses of calcium chloride, calcium gluconate and digalen, administered intravenously. Dogs from stock and others especially prepared were used. The carotid artery was cannulized and a pneumograph applied to the chest to record the pulse and blood pressure and respirations respectively. In the first group, ten normal dogs were used. Fifteen per cent of the calculated lethal dose of calcium chloride or gluconate produced only a transient slowing of the pulse and a slight drop in blood pressure. When this dose was preceded by therapeutic doses of digalen, i.e., sufficient to produce changes in the pulse or blood pressure, definite toxic effects were obtained. Periods of asystole, extrasystoles, marked slowing of the pulse and fibrillation were observed.

Following the administration of digalen, approximately 30 to 40 per cent of the calculated lethal dose of calcium gluconate was given. After a brief rise in blood pressure there was an abrupt and dramatic cessation of heart action and the blood pressure fell to zero. Similar results were obtained with calcium chloride (figs 1 and 2).

On the other hand, after administration of sufficient calcium ions to produce definite circulatory changes (approximately 30 per cent of the calculated lethal dose), digalen in large doses gave no such results, and only when the full lethal dose of digalen was reached did the blood pressure fall and the circulation fail (figs 3 and 4).

A second group of five dogs was especially prepared by subtotal hepatectomy (an average of 80 Gm of liver per dog being removed) to simulate liver damage in case 1. While these dogs were more sensitive to small doses of either calcium ions or digalen than normal dogs, it is questionable whether their general physical condition was not to blame, rather than especial sensitivity produced by liver damage. Even with administration of dextrose, these animals live only a few days after operation.

A third group of six dogs received chloroform anesthesia, one-half hour for two successive days, as a preliminary preparation, to produce liver damage. The results did not differ essentially from those obtained in normal animals.

We feel that the results of these experiments, in conjunction with the reports of other writers, justify the conclusion that the administration of calcium salts intravenously, following the administration of digitalis or one of its purified proprietary modifications, is a procedure of considerable hazard and may result in avoidable fatalities.

#### SUMMARY

1 Two deaths occurred following the intramuscular administration of digitalis and the intravenous injection of calcium gluconate chloride.

2 The manufacturers of calcium gluconate or chloride should preface their literature with a warning relative to the additive effect of calcium and digitalis when given simultaneously.

## OBLITERATIVE VASCULAR DISEASE

### REPORT OF FIFTY-ONE CASES TREATED WITH PASSIVE VASCULAR EXERCISE

J HERBERT CONWAY, MD

NEW YORK

The introduction of passive vascular exercise in the treatment of obliterative vascular disease has stimulated renewed interest in the care of patients suffering from symptoms due to impaired peripheral circulation. The idea of applying environmental pressure changes to an extremity in order to increase the flow of blood through it has been advanced by Reid and Herrmann<sup>1</sup> and by Landis and Gibbon<sup>2</sup>. One of the units for passive vascular exercise, designed by Herrmann, has been in use for the past year in the surgical and physical therapy departments of the New York Hospital. This unit differs from the apparatus designed by Landis and Gibbon chiefly in that the environmental pressure changes are produced slowly rather than suddenly. It is believed that rhythmic, gradual change from negative to positive pressure augments the flow of blood through an extremity just as effectively as does rhythmic sudden alternation in environmental pressure and does so without danger of injury to the intima of the vascular network, the vessels of which have already undergone some degree of sclerosis and thrombosis.

From the Department of Surgery of the New York Hospital and Cornell Medical College.

The skepticism with which this ingeniously devised machine was received by the profession here gave way to interest after the spectacular demonstration of its value in a classic case of embolus of the femoral artery one year ago. Since that time approximately ninety patients have been given passive vascular exercise, of these only fifty-one were observed a sufficiently long time and were given enough hours of treatment to permit a fair evaluation of the clinical effects of the exercise on the course of the disease. It is my opinion that this recently developed therapeutic measure has justified its inclusion in medical therapeutics. In defense of this belief I shall report the results obtained with it.

in different types of peripheral vascular disease. The principles and mechanism of the machine have been described by the inventor and a detailed account of the management, from an institutional point of view of the patients treated at the New York Hospital is to be published elsewhere.<sup>3</sup>

## SELECTION OF CASES

With regard to the selection of cases it may be said that every patient was subjected to a complete examination before passive vascular exercise was instituted. The symptoms of the disease were carefully noted and the physical examination included palpation of the peripheral pulses, determination of the presence or absence of Buerger's sign, oscillometric studies, roentgenograms of the feet, electrocardiograms when indicated, and skin temperatures with a record of vasospastic indexes in certain patients. During the period of observation on which this study is based, passive vascular exercise was employed without other treatment save the incision of the skin, the care of the nails and other simple measures advocated by Reid.<sup>4</sup> Dispensary and hospital patients were treated in the physical therapy department of the New York Hospital; their progress was observed by one physical therapist and they were daily attended by the same nursing staff. This centralization of treatment increased its efficient execution and simplified the evaluation of results.

## CLASSIFICATION

The classification used by de Takats<sup>5</sup> in a recent publication has been adopted in the presentation of these cases of peripheral vascular disease. Table 1 shows the distribution of the fifty-one patients according to this classification.

**GROUP 1—Arteriosclerosis Obliterans**—In this group there were thirty-six patients. Only those who were found to have predominant involvement of the

major or secondary arterial pathways were selected from some seventy patients with the general signs of peripheral arteriosclerosis and the complaint of intermittent claudication or rest pain. The selection was based on preliminary examinations and on observations of the early response to treatment. Calcification of the large vessels as determined by roentgen examination and diminished or absent oscillometric pulsations were considered evidence of impairment of the major or secondary arteries of the extremity. Vasodilatation, as demonstrated by a rise in the surface temperature following interruption of the sympathetic pathways, was accepted as an indication that the arterioles and capillary bed had not undergone diffuse sclerosis. Passive exercise was given for a period varying from three to six months to the thirty-six patients constituting a group of cases, which according to opinions expressed by earlier writers could be considered ideally suited for this treatment. The results obtained are given in table 2.

Fourteen of the thirty-six patients were ambulatory and twenty-two were hospitalized for treatment. The ambulatory patients were given from one and one-half hours to two hours of treatment four times a week. Eleven or 78.5 per cent were relieved of major symptoms and could be classified as definitely improved. Rest pain was less severe, intermittent claudication came on less rapidly, toe joint mobility was increased, subcutaneous thickening was less evident. Buerger's sign became less strongly positive, and the patients exhibited a definitely improved morale. Of the twenty-two patients who were hospitalized for treatment, eighteen, or 81.8 per cent, were improved. Toe amputation was necessary in three cases in this series but the end result was one of general improvement in the condition of the extremity. In two cases skin grafts were applied to healing areas. Passive vascular exercise seemed to have a distinctly favorable effect on the healing of the grafts. In seven cases there were arteriosclerotic leg ulcers. Four of these responded well to the treatment in three cases in which there was no improvement, amputation of the leg was carried out. The method adopted for selection of cases excludes a

TABLE 2—*Result of Treatment of Thirty Six Patients Having Predominant Involvement of Major or Secondary Arterial Pathways*

Result	Number of Cases	Percentage
Improved (no amputation)	26	72.2
Improved (toe amputation)	3	8.3
Improved (major amputation)	0	0.0
Unimproved (no amputation)	3	8.3
Unimproved (toe amputation)	0	0.0
Unimproved (major amputation)	4	11.1
<b>Total</b>	<b>36</b>	<b>100.0</b>

large number of arteriosclerotic subjects. It is believed that the high percentage of good results obtained in the cases reported here can be attributed to the careful choice of patients for treatment.

The most spectacular result was obtained in a man, aged 67, who exhibited signs of disease of the coronary arteries and who also was completely invalidated because of intermittent claudication. Excruciating leg pains became manifest when he walked a distance of only 12 feet. He could stand no longer than two or three min-

utes before the same pain necessitated recumbency. His chief concern was the fact that he could not remain standing twelve minutes the time needed to complete his daily shave. He was hospitalized and given two hours of treatment a day to both legs for a period of three months. Improvement was definite though gradual and at the time of his discharge from the hospital he could walk 300 feet and could stand from twenty to thirty minutes without pain. For the past four months this patient has been without treatment as he has returned to his home in a distant city. Subjective improvement has been maintained.

Several patients in this group were observed to experience pain during treatment especially during the negative pressure phase. This complaint was considered a contraindication to passive vascular exercise and was interpreted as evidence of fixed sclerosis of the arterioles. Three patients in the series experienced pain and in all three a radical amputation was later done for advancing gangrene and uncontrollable pain. Despite the fact that preliminary observations seemed to indicate that the smaller vessels were distensible, the amputated extremity showed advanced sclerosis not only of the major and secondary arteries but of the arterioles as well. This experience confirmed the opinion of other observers that vascular exercise is not beneficial in cases of advanced diffuse arteriosclerosis of the extremity. It was in one of these three patients that gas bacillus infection developed postoperatively in the midthigh amputation stump with a resulting surgical mortality. The patient, aged 64, was diabetic and had an open ulcer at the site of the toe amputation. The wound had been treated with dilute solution of sodium hypochlorite for many days and microscopic examination of smears from its surface showed no organisms. Passive vascular exercise had been given daily for two weeks in an effort to aid the healing of the wound to control pain and to prevent the extension of gangrene. As stated before the treatment caused the patient pain and was consequently discontinued. At the time of the amputation there was an unhealthy appearance of the skin in the midthigh region as if the rubber cuff applied to the thigh had caused local trauma. By some observers this slight trauma has been considered a possible contributory factor in the development of the Welch bacillus infection. Since this occurrence it has been demonstrated in this clinic that the rubber cuff, if properly applied, need not cause the slightest degree of pressure on the tissues of the thigh.

In my experience only a small number of patients with arteriosclerotic vessels of the lower extremity, who show good oscillometric readings can be expected to respond favorably to passive vascular exercise. In cases showing poor oscillometric pulsations a plan has been adopted whereby a trial period of treatment consisting of from eighteen to twenty-four hours is given in twelve sessions. If symptoms are alleviated and the extremity shows even slight improvement the course of treatment is extended. The results obtained in this group of patients have been very encouraging. The opinion is held that passive vascular exercise is the best available method for developing collateral circulation in an extremity the viability of which is threatened by advancing arteriosclerosis affecting chiefly the major and secondary arterial pathways. In only a few cases has an improvement in oscillometrics been observed.

**GROUP 2—Acute Vascular Occlusion** (thrombosis, embolism, operative ligation of arteries)—There were ten patients in this group. In four the treatment was instituted shortly after the acute episode. In four, passive vascular exercise was given to aid in the establishment of collateral circulation, the first symptoms having occurred from seven to ten days earlier. The result of treatment was good in three of these. Amputation was done in the fourth. Two patients had suffered bilateral femoral arterial emboli, had been treated with passive vascular exercise as an emergency measure in another institution, and had been referred here for subsequent care, to aid in maintaining the collateral circulation that had developed.

Detailed reports of the four cases in which treatment was instituted shortly after the onset of the acute episode follow.

The first patient was a man, aged 50, who was admitted to the hospital because of embolic gangrene of the right leg with adjacent cellulitis. Guillotine midthigh amputation was performed and forty-eight hours after operation the patient developed the signs of embolus of the left femoral artery. Pulses were absent at the femoral, popliteal, dorsalis pedis and posterior tibial arteries. Oscillometric examinations showed no pulsations at all in the thigh, calf or foot. The leg very rapidly exhibited a mottled bluish white discoloration. Arterial embolectomy or amputation would undoubtedly have been resorted to had not the constant application of passive vascular exercise brought about the development of adequate collateral circulation. Three hours after the treatment was started, the color of the leg had returned to almost normal. After seventy-two hours of continued passive vascular exercise the extremity appeared normal and treatment was discontinued, though the femoral, popliteal, post-tibial and dorsalis pedis pulses still were not palpable. The left leg remained free from symptoms or signs of impairment of the circulation. The patient died suddenly two months later in an attack of coronary artery disease. A mural thrombosis was demonstrated at autopsy.

The second patient was a man aged 79, who was admitted to the hospital ten days after the sudden onset of pain in the right leg. The patient complained of dizziness at the time of the onset of pain. Examination of the lower extremities at the time of admission to the hospital showed that there was a distinctly demarcated area of bluish discoloration involving the great toe and the toe adjacent to it on the right foot. The discoloration also extended up over the dorsum of the foot. The femoral arterial pulse was palpable on the right side, but no pulsations could be felt below that level. Oscillometric examination showed no evidence of pulsation. The skin temperature over the right great toe was 20 C (68 F). Pulses in the left leg were apparently normal. This case was interpreted as one of sudden thrombosis of the popliteal artery of the right leg. Ten hours of passive vascular exercise was given daily for ten days after which the treatment was diminished to three hours daily. After twenty-one days the nutrition of the right leg seemed quite adequate and as good as that of the left although the peripheral pulses were not palpable. The patient walked about without undue discomfort, and regional discoloration of the foot had disappeared.

The third patient was a man aged 52, an Italian, who was admitted to the hospital because of multiple aneurysms involving the subclavian axillary, femoral and popliteal arteries. The etiology of the aneurysms has not definitely been determined. The case will be reported elsewhere. Surgical intervention seemed indicated as the left femoral aneurysm had enlarged rapidly and had shown a "weeping hemorrhage" through the stretched integument over its surface. To avoid the rupture of the aneurysm with possible fatal hemorrhage the left common iliac artery was ligated. This was the only accessible proximal vessel, for the false aneurysmal sac had eroded into the pelvic area. At the close of the operation, pulsation in the aneurysm had ceased. The left foot had assumed a mottled, cyanotic appearance. The skin tempera-

ture had dropped. Passive vascular exercise was instituted at once and continued for three days. In this case the nutrition of the left leg was never markedly disturbed but it may be assumed that the passive exercises aided markedly in the rapid development of collateral circulation.

The fourth patient was a Jewess, aged 69, who was admitted to the hospital in a state of collapse. The diagnosis of mural cardiac thrombus was made. Shortly after admission the patient developed the classic signs and symptoms of embolus of the femoral artery. Passive vascular exercise was instituted at once and kept up continuously for three days, the circulation and nutrition of the leg improved promptly and seemed fairly well maintained throughout this time. However, the patient died suddenly from a pulmonary embolus. Permission for postmortem examination was not granted.

**GROUP 3 — *Thrombo-Angutis Obliterans*** — Four patients suffering from Buerger's disease were treated by passive vascular exercise. Two of these are reported as unimproved after three weeks of treatment. A third patient was a 34 year old Gentile who had failed to improve after two months of treatment, in fact, the degree of rest pain increased and a gangrenous area of the toe extended. This patient's condition later responded very well to daily intravenous injections of sodium citrate solution. In the fourth case, passive vascular exercise was resorted to in order to promote healing of pinch grafts placed over a granulating ulcer. After one month the grafts had healed well and treatment was discontinued. Passive vascular exercise was of doubtful value in this case.

**GROUP 4 — *Syphilitic Endarteritis*** — Treatment was given to only one patient in this group, a man, aged 60 who had been given antisyphilitic treatment irregularly over a period of twenty years. Intermittent claudication of six weeks' duration with absence of peripheral pulsations in the left leg in a syphilitic subject justified the diagnosis of syphilitic endarteritis. Passive vascular exercise was instituted with some symptomatic relief and a slight increase in the oscillometric readings.

#### SUMMARY

1 Fifty-one cases of organic vascular occlusion of the lower extremity were treated with passive vascular exercise.

2 Experience with these cases supports the contention that treating organic vascular obstructions by an intermittent negative pressure environment is physiologically sound.

3 Passive vascular exercise, given with the apparatus of Hermann, caused improvement in 80.5 per cent of thirty-six cases of arteriosclerosis obliterans affecting the major and secondary arteries of the extremity. In nine of the ten cases of sudden vascular occlusion, the treatment given was effective. In four cases of thrombo-angutis obliterans, no benefit was derived from passive vascular exercise. In one case of syphilitic endarteritis, the treatment was followed by moderate improvement.

4 In no case was there conclusive evidence that passive vascular exercise had, in and of itself, caused serious complications.

525 East Sixty-Eighth Street

**The Apex Beat** — If one places the patient in a good light it is as a rule comparatively easy to ascertain the position of the apex beat of the heart — Dr E. J. G. Beardsley, quoted by Fisher, Alexander. *Aphorisms in Clinical Medicine*. *Canad J Med & Surg* 77: 166 (June) 1935.

## THE GORDON TEST FOR HODGKIN'S DISEASE

DAVID H. ROSENBERG, MD  
AND  
LEON BLOCH, MD  
CHICAGO

In 1932 Gordon<sup>1</sup> reported the observation of a meningoencephalitic syndrome following the intracerebral inoculation of rabbits and guinea-pigs with a sterile suspension prepared from lymph nodes of typical Hodgkin's disease and in the ensuing year<sup>2</sup> suggested this procedure as a valuable diagnostic aid. Van Rooyen<sup>3</sup> and other English investigators<sup>4</sup> have corroborated this work and have affirmed the specificity of this test. From the reports in the literature (summarized in the accompanying table) the test has been applied in seventy-seven cases of Hodgkin's disease and has been found positive in fifty-six instances (77.9 per cent). Of 101 controls, consisting of normal lymph nodes and nodes showing carcinoma, sarcoma, lymphosarcoma, "pseudoleukemia," leukemia, tuberculosis, lymphoid hyperplasia and adenitis, the test was negative in ninety-eight cases (97 per cent), the three positive tests having been reported recently by Manson,<sup>5</sup> two of which were cases of tuberculous lymphadenitis and one was of lymphoid hyperplasia.

At this time we record our results with three cases of Hodgkin's disease and with three other lymph nodes used as controls (metastatic adenocarcinoma, aleukemic lymphadenosis, lymphoid hyperplasia). A summary of the literature is included in this report.

#### GORDON'S TEST

**Method** — With aseptic precautions a lymph node is collected in a sterile test tube or petri dish. One or more grams is placed in a small sterile mortar under cover and the rest of the node is kept in a refrigerator. The tissue is cut into very small pieces and is ground into a fine emulsion, nutrient broth of pH 7.1-7.2 being added to make a 1:10 suspension. It is maintained in a refrigerator at from 0 to -4 C. for seven to ten days, and, before using, is tested for sterility aerobically and anaerobically. All lymph nodes in this study were obtained from live patients. If necropsy material is studied, the node should be removed aseptically, disinfected with absolute alcohol, and dipped into boiling water and then into ether. Phenol (0.5 per cent) may be added to the broth as a further precaution against contamination.<sup>3a</sup>

Of rabbits lightly anesthetized with ether, a short incision is made in the scalp and a tiny opening is drilled in the skull at a point 2 mm. lateral to the sagittal suture and 1.5 mm. anterior to the lambdoidal suture.<sup>3a</sup> Through this opening, 0.4 cc. of sterile suspension is slowly injected into the occipital lobe to a

<sup>5</sup> Manson M. H. *Biological Phenomena in Hodgkin's Disease*. *Minnesota Med.* 18: 263 (April) 1935.

depth of about 3 mm by means of a short fine needle. The skin is then sutured and the wound covered with collodion. In addition, 0.6 cc of the inoculum is injected into the marginal ear vein. The rabbits are weighed before the inoculation and daily thereafter.

**Positive Test**—After an incubation period of from two to six days (in one rabbit, sixteen days<sup>1</sup>), slight impairment of locomotion sets in, followed by a progressive spastic paralysis of the hind limbs. The gait becomes decidedly ataxic, and the animal may stagger and fall. In the more marked reactions retraction of the head, opisthotonos and convulsive movements are observed. Van Rooyen<sup>2a</sup> reported nystagmus, grinding of the teeth and urinary and fecal incontinence in some animals. Progressive wasting and weakness affecting particularly the hind quarters, are found in all cases. Death occurs frequently within three days to one month, usually in ten days. A larger number recover completely or pass into a chronic state.

At autopsy, gross examination reveals only a slight hyperemia of the meninges. Microscopically, usually little or no cellular infiltration in the brain is found, but with more active material Gordon noted a lympho-

a moderate anemia. Roentgenograms of the chest showed a large mediastinal mass. Biopsy of a cervical node revealed typical Hodgkin's disease.

Two rabbits were inoculated with a suspension that had been refrigerated for eleven days. Except for a gain in weight, no effects were noted. Two other rabbits were inoculated with the same suspension after thirty-two days of refrigeration. Again the test was negative.

**CASE 3**—H. H., a white woman, aged 22, presented the clinical picture of a typical Pel-Ebstein form of Hodgkin's disease, enlargement of the lymph nodes (left cervical and axillary) first appearing three months before hospitalization. Blood examination showed erythrocytes, 2,680 million, hemoglobin, 47 per cent (Sahli), leukocytes, 5,400, differential formula, normal. Maximum temperature, 103.8 rectal. Chest roentgenograms were normal. Biopsy of an axillary node showed Hodgkin's disease.

Two rabbits were inoculated with a suspension that had been refrigerated for ten days. One rabbit had been too deeply anesthetized and died twelve hours later. The other developed weakness of the hind limbs on the third day, followed by spastic paralysis of the hind limbs, slight spasticity of the fore limbs, increasing ataxia and loss of weight. On the fifth day, cervical rigidity and convulsive seizures were noted. The animal died on the sixth day. Autopsy revealed a hyperemia of the meninges. The brain was normal on microscopic examination. Aerobic and anaerobic cultures of the brain and meninges were negative.

**Controls**—Case 1. Biopsy revealed adenocarcinoma. Two rabbits were inoculated with a suspension ten days old. No effects were noted after four weeks of observation.

**CASE 2** Biopsy revealed lymphoid hyperplasia. Two rabbits, inoculated with a suspension fifteen days old, showed no abnormal effects after four weeks of observation.

**CASE 3** Biopsy revealed aleukemic lymphadenosis. Two rabbits were inoculated with a suspension ten days old. No effects were noted.

#### PROPERTIES AND NATURE OF THE PATHOGENIC AGENT

The extensive studies of Gordon<sup>1</sup> supplemented by those of Van Rooyen, have yielded interesting data pertaining to the characteristics of the pathogenic agent. It has been found in an active state several weeks after refrigeration at 0 to -4 C, and for at least six months and as long as two years after desiccation. It is relatively thermostable, resisting temperatures of from 65 C<sup>1</sup> to 73 C<sup>4</sup> for thirty minutes. When refrigerated it resists 0.5 per cent phenol for at least two weeks and 10 per cent ether for seventeen days, although the activity is decreased by the latter disinfectant. It is not inactivated by freezing suspensions to -190 C for ten minutes or tissue desiccates to -190 C for twelve hours or by exposure to ten skin unit doses of x-rays. Alkalis such as sodium hydroxide, sodium bicarbonate, ammonia or ammonium carbonate may reduce its pathogenicity considerably. Its activity is greatest when the  $p_H$  of the broth medium is from 6.8 to 7.3, the optimum being attained with phosphate buffered broth of  $p_H$  7.1<sup>4a</sup>. That the pathogenicity is increased by refrigeration, probably through autolysis of tissues, was an early observation of Gordon<sup>1</sup>. Later, Van Rooyen<sup>4a</sup> noted that its activity may be enhanced by maintaining the suspension at 37 C or by intense freezing in liquid air followed by rapid thawing. The agent seems to be present in a more active state or in greater amounts during the early or acute stage of the disease. But no correlation between the varied pathogenicity in different cases and the presence of any particular type of cell appears evident. It has been suggested that perhaps the larger proportion of fibrous tissue accounts for the lesser amount or absence of the agent in more chronic cases.

Summary of Results with Gordon's Test

cytic meningitis and perivascular lymphocytic infiltration in the brain substance. No inclusion bodies have been described<sup>4a</sup>. Cultures of the brain and meninges are sterile.

#### REPORT OF CASES

**CASE 1**—J. S., a white man, aged 35, complained of generalized itching of the skin of four months duration and a loss of 8 pounds (3.6 Kg.) in two weeks. Many larger and smaller, firm, discrete, movable, nontender lymph nodes were found in the supraclavicular fossae and in the right posterior cervical and subaxillary regions. A mediastinal mass was noted on roentgen examination. Herpes progenitalis was present. Biopsy of a cervical node revealed typical Hodgkin's disease.

Two rabbits were inoculated with a suspension that had been subjected to twenty-three days of refrigeration. Generalized weakness with slight spasticity of the hind limbs set in on the third day. Increasing ataxia and spasticity developed, and the animals became progressively weaker and lost weight. One rabbit died on the ninth day, the other on the tenth day after inoculation. Autopsy revealed hyperemia of the meninges. Sections of various parts of the brain showed no abnormal histologic manifestations. Aerobic and anaerobic cultures of the brain and meninges were negative.

Two control rabbits, inoculated with broth containing 0.5 per cent phenol, remained in perfect condition and gained in weight.

**CASE 2**—C. S., a white youth aged 17, complained of painless "swellings in the neck" which first appeared one year before and progressively increased in size. The supraclavicular, posterior cervical and right axillary nodes were firm, discrete, movable and considerably enlarged. Retromanubrial dullness was increased and widened. The spleen descended 2 cm. below the costal margin on inspiration. Blood examination revealed

Aerobic and anaerobic cultures of the tissues and suspensions, as well as of the brain, meninges and heart's blood of rabbits manifesting a positive test, have been consistently negative. Gordon<sup>2</sup> has reported the finding, on stained films, of "spherical granules" closely resembling Paschen bodies. This has been confirmed by Coles<sup>6</sup> recently. By a special technic Van Rooyen<sup>4b</sup> has adequately demonstrated the filtrability (Berkefeld, Seitz) of the agent.

Attempts to transmit the pathogenic factor from one rabbit to another have been uniformly unsuccessful. Some rabbits, when completely recovered, were found to be immune to a second dose of the same material, others, on the contrary, were more susceptible to reinoculation.<sup>4a</sup> In one rabbit, an immune serum capable of inactivating the pathogenic agent was obtained,<sup>2</sup> further studies of a like nature have not been recorded.

Thus far, the nature of the pathogenic factor is unknown. Gordon<sup>2</sup> considered it a virus, but the inability to transmit the experimental disease as well as the observation of an increased susceptibility to reinoculation of recovered rabbits, does not support this hypothesis. The finding of neutralizing antibodies in the serum of a recovered rabbit is of interest and needs confirmation.

More recently, Friedemann and Elkeles<sup>8</sup> observed a clinical syndrome produced in rabbits by the intrathecal or intracerebral inoculation of normal human bone marrow, spleen or leukocytes, a syndrome which bore a striking resemblance to that following the use of suspensions of Hodgkin's nodes. They felt that these symptoms might be due to the action of the proteolytic enzyme of Jochmann and Lockmann and suggested its identity with the encephalitogenic factor in Hodgkin's disease. Studying this relationship Mackenzie and Van Rooyen<sup>9</sup> concluded that the two factors are not identical. Further they obtained no evidence indicating a proteolytic action on brain tissue by the agent in Hodgkin's disease. Van Rooyen<sup>4a</sup> suggested that the latter agent may be a neurotoxin, having a predilection for the brain tissue of rabbits and guinea-pigs. That the symptoms are not due to trauma seems well established.<sup>3a</sup>

#### COMMENT

Prior to the report of Manson,<sup>5</sup> the Gordon test appeared to be specific for Hodgkin's disease for the presence of an encephalitogenic agent in normal bone marrow, spleen or leukocytes (pus) does not militate against the significance of a similar agent restricted to the lymph nodes of this disease. Hence the uniformly negative controls reported by other investigators prompts the question whether the two Gordon positive cases of tuberculous adenitis contained any pus and furthermore arouses interest in the ultimate course of the positive case of "hyperplasia".

Since about one fourth of the reported cases of Hodgkin's disease gave negative tests, and since the positive tests were more frequently observed in early or acute cases, the value of Gordon's test if ultimately

proved, seems to be limited to the diagnosis of early or histologically atypical cases. Further trial by different investigators is essential, however, before it will be possible to pass final judgment on its usefulness or specificity.

#### SUMMARY

1. Gordon's test was positive in two cases of early Hodgkin's disease and negative in a chronic case of one year's duration. Three abnormal lymph nodes, used as controls, gave negative tests.

2. A more extensive trial by different investigators is advocated, in order that the significance of the test may be properly evaluated.

## THE TEMPERATURE OF THE SKIN SURFACE

WILLIAM BIERMAN, M.D.

NEW YORK

The temperature of the surface of the skin varies with the environmental temperature, with the temperature of the body and with conditions in the skin and in the structures lying beneath it.

#### VARIATIONS IN DIFFERENT REGIONS OF THE SKIN

In a comfortable environment, the temperature of the skin surface varies in different regions of the body. The temperature of the skin surface of the trunk usually varies between 33.5 and 36.9 C (92.3 and 98.4 F).<sup>1</sup>

The temperature of the skin surface is lower over superficial veins than it is over superficial arteries. It is lower over protruding and markedly curved parts, such as the nose, ears, fingers and toes. The temperature of the skin is higher over muscles than over bone or tendons over an active organ than over one at rest.<sup>1</sup> As a rule stout persons (because of their thicker layer of subcutaneous fat) have a much lower skin temperature than thin ones.<sup>1</sup> The symmetrical areas are kept at about the same temperature. Usually these areas differ within 0.5 and 1 degree C.<sup>1</sup> I have observed even greater temperature differences of the skin surface of the symmetrical regions of the body. This would indicate that these areas may vary somewhat in their physiologic activity as well as in their configuration.

In general, the temperature of the skin covering the extremities is lower than that of the skin covering the head and the torso. The skin surface temperature of the extremities also shows the greatest fluctuations when the body is exposed to changing environmental temperatures. When there is the possibility that the body temperature may rise because of an increase in metabolism or because of the high temperature of the surrounding medium, the skin surface temperature of the extremities increases so that it may approach or actually reach the same temperature level as that which

exists over the head and torso. On exposure to cold, the skin surface temperature of the extremities becomes much lower than that of the rest of the body. I have observed the skin surface temperature of the toe to go as low as 15 C (59 F) on exposure to cold and as high as 45 C (113 F) on exposure to heat.

While the temperature of the exterior of the body fluctuates widely, that of its interior varies between narrow limits. Indeed, it would appear as if the pur-

Cohn and Steele<sup>12</sup> noted the occurrence of fever in a case of heart failure in which no pathologic condition other than cardiac was present to account for the temperature elevation. A possible explanation which they offer is that the elevation of the temperature of the interior of the body is due to a slowing of the blood flow to the surface as well as to other parts.

#### VARIATIONS DURING FEVER

In fever the temperature gradient of the skin surface that normally obtains disappears, so that the temperatures of the various parts of the skin surface of the body reach a more or less common level. When fever is produced by physical means through the application of heating energies, the temperature gradient of the skin surface disappears even before the internal temperature (as judged by the rectal thermometer) begins to rise. As the body temperature becomes more elevated the skin surface temperature rises and at high temperatures such as for example, around 106 F (41.1 C) the temperature gradient may become reversed, i. e., the temperature of the skin surface of the toes may go higher than the temperature of the skin surface of the torso (chart 1).

When the body supplies its own energy to create a fever (as after the intravenous injection of typhoid vaccine) the skin surface temperatures, particularly the temperature of the toes, may remain as they were originally or they may even go lower, while the internal temperature is being elevated. This is the period in which the subjective sensation of a chill occurs. After the systemic temperature elevation has become established, the skin surface temperature rises. During defervescence of the fever the skin surface temperature of the toes may remain comparatively high, so as to encourage the loss of heat to the environment. If the objective of a therapeutic fever is to increase the blood flow in a case of insufficient peripheral circulation it

Chart 1—Skin surface temperature in fever following the use of diathermy and phototherapy for gonorrheal salpingitis in a woman aged 28

pose of the marked variations in skin surface temperature is to keep the temperature of the interior relatively constant. There is a continual balancing between heat production and heat loss.

#### INFLUENCE OF AGE

Age has an influence on skin surface temperatures. With old age the temperature becomes lower. Basal metabolism diminishes with increasing years.<sup>5</sup> In children, Kunkel<sup>2</sup> and Talbot<sup>6</sup> state that skin surface temperatures are lower than in the adult, while Cobet<sup>4</sup> describes higher temperatures. The heat regulating apparatus is not fully developed at birth and is almost completely absent in the premature infant. The temperature of the skin of the premature infant as well as that of the body, is affected directly by the surrounding temperature and to a greater extent than it is in the normal infant.

#### EFFECT OF CHANGES IN METABOLISM

The close connection between the temperature of the extremities and the heat dissipating mechanism is shown by the fact that under constant environmental conditions a simple linear relationship is found between the temperature of the great toes and the basal heat production per unit of surface area.<sup>8</sup> There is a diurnal variation in the skin surface temperature of the feet.<sup>9</sup>

Muscular exercise influences the temperature of the skin. During the first few minutes of exercise the temperature of the skin falls and later rises.<sup>10</sup>

Psychic factors may influence the temperature of the surface of the skin. In cases of hyperemia of the face due to excitement, there occurs a rise in the skin surface temperature over the cheeks.<sup>11</sup>

Chart 2—Effect of forearm in hot water (43.5 C) and left leg constricted in cuff with pressure of 60 mm of mercury in a normal woman aged 21

would seem more rational to produce fever by physical means, since the initial stage of vasoconstriction is avoided.

#### VARIATIONS IN HEAT TOLERANCE IN DIFFERENT PARTS OF THE BODY SURFACE

There is a marked difference in the heat tolerance of various parts of the surface of the body. The extremities, which are normally more responsive to changes in systemic temperature, also appear to possess greater

sensitivity toward an increase in their normal temperature, i. e., they have the lowest tolerance temperatures. In general, those portions of the body surface which have the lowest tolerance temperatures are also characterized by their ability to endure heating for the longest periods. In fact, the tolerance time and the tolerance temperature rise are approximately in inverse ratio. The ability of the skin of the forehead, of the feet and of the hands to tolerate heat better than other parts of the skin surface of the body and yet maintain lower temperatures may possibly be explained by increased sweating of these parts, by the presence of

Chart 3—Reaction to acetylsalicylic acid (10 grains or 0.6 Gm) of a normal woman aged 26. A acetylsalicylic acid

arteriovenous anastomoses, and by the greater number of thermal nerve endings.<sup>13</sup>

#### EFFECT OF COLD

When cold is applied to a local area, the skin surface temperature in that area falls quickly. On the application of an ice bag, for example, the skin temperature may be diminished 20 degrees C (36 degrees F) within a quarter of an hour and may reach a minimal 5 to 6 C (41 to 42.8 F) in from forty to sixty minutes. By conduction the effect may extend to the underlying tissues.<sup>14</sup> On immersion of the body in cold baths, the internal temperature may at first rise a few tenths of a degree.<sup>14</sup> The subsequent course of the temperature varies with the constitution of the individual, the thickness of the subcutaneous fat layer and the length of time of immersion.

#### SKIN SURFACE TEMPERATURE AS A DIAGNOSTIC METHOD FOR DETERMINATION OF VASCULAR STATUS

The ability of the skin surface temperature of the extremities to fluctuate widely makes it possible to evaluate the vascular status of these parts. If one forearm is immersed in water at 110 F (43.3 C) it is possible to observe a rise in the skin surface temperature of the toes in a normal subject.<sup>15</sup> I have observed that in a normal subject the temperature of the skin of the great toe rises to approximately the same level as the skin surface temperature of the forehead. This rise in the skin surface temperature of the toe is due to the activity of the thermoregulatory mechanism in its effort to resist the elevation of body temperature

that would occur if the body did not utilize its ability to increase heat dissipation by augmenting the vascular flow to the extremities.

If this flow is interfered with, as by causing a constriction of the normal leg with a cuff inflated to the equivalent of 60 mm pressure, no rise or a much restricted one occurs in the temperature of the toes (chart 2). The inability of the toe temperature to rise under these circumstances also occurs when the circulation has been restricted by some pathologic condition, such as arteriosclerosis, thrombo-angitis obliterans, varicose veins or embolism.

If the forearm is immersed in very cold water, it will be observed that the temperature of the skin surface of the toe becomes lower. Under these conditions the body is evidently endeavoring to maintain its temperature level by shutting down on heat loss. In the presence of sufficiently severe vascular pathologic changes, such as arteriosclerosis and thrombo-angitis obliterans, the skin surface temperature of the toe does not go lower in response to the application of cold applied to the forearm.

When air heated to about 100 F (37.8 C) is applied by means of a thermostatically controlled heating hood, it is observed that the skin surface temperature of the toe rises to about the same level as the skin surface temperature of the forehead. When the normal leg is constricted by means of a cuff inflated with air to a pressure of 60 mm of mercury so as to embarrass the venous return, the toe temperature rises more slowly and does not reach as high a level as in the unconstricted leg. In cases of venous disturbance, as in varicose veins and phlebitis, the skin surface temperature response to direct heating is lower than in the normal. In cases of arteriosclerosis, on the other hand, the skin surface temperature of the toe frequently rises above that of the forehead. In thrombo-angitis obliterans, because the pathologic processes involve both veins and arteries, the temperature response of the toe may resemble that of the normal. When the pathologic process primarily involves the veins (as in varicosities)

Chart 4—Effect of coffee (two cups) on a normal man aged 20

or the arteries (as in arteriosclerosis), it is possible to make the diagnostic differentiation by observing the changes in the temperature of the skin surface of the toe when the leg is exposed to heat directly.

The direct application of cool air to the lower extremities rapidly causes a drop in the skin surface temperature of the toes. This response is delayed and diminished in the presence of vascular disease, such as in arteriosclerosis and thrombo-angitis obliterans.

The application of cold and heat locally and at a distance puts the vascular machinery "under a load," as it were, permitting one to gain a still more definite idea of the integrity of the peripheral circulation.

#### THE USE OF SKIN TEMPERATURE IN DIFFERENTIATING BETWEEN ORGANIC OCCLUSION AND VASOSPASM

Observations of changes in the skin surface temperature of the toes in differentiation between vasospasm and organic occlusion have been made by several men. It has been shown that the removal of the sympathetic vasoconstrictor influence caused an elevation of the skin surface temperature of the extremities when vasospasm existed but not when occlusive organic disorder was the cause of the vascular difficulties.<sup>16</sup> The sympathetic vasoconstrictor influence may be removed by the induction of anesthesia, either general, spinal or local.<sup>1</sup>

#### THE USE OF SKIN TEMPERATURE AS A DIAGNOSTIC PROCEDURE IN CONDITIONS OTHER THAN PERIPHERAL VASCULAR DISEASES

The temperature of the skin may be used as an aid in the diagnosis of conditions other than those of peripheral vascular diseases.

The temperature of the skin surface has been measured for its diagnostic value in several neurologic conditions. It has been found possible to differentiate between fever of central origin and other types of fever by noting the difference in the temperature of the skin surface.

There is a relationship between vascular supply and the psychic centers, as indicated by experiments in which the surface temperature of circumscribed skin areas was raised by suggestion in hypnosis.<sup>18</sup>

I have noted that while high skin surface temperatures are found in the region of joints during the presence of an acute arthritis, low surface temperatures occur over the joints in chronic arthritis. Others have made similar observations.<sup>19</sup>

Information concerning the temperature of the skin surface may prove of value to the dermatologist. Thus observations of the surface temperature in areas of alopecia areata show no essential difference between these areas and the adjoining normal skin, indicating that this condition is not due to restriction of local blood supply.<sup>20</sup> Changes in skin surface temperature occurring in leprosy have been described.<sup>21</sup>

#### SKIN SURFACE TEMPERATURE CHANGES AS A METHOD FOR EVALUATING THE THERAPEUTIC INFLUENCE OF DRUGS AND PHYSICAL MEASURES

The local skin surface temperature is affected by the rate of capillary circulation.<sup>22</sup> This permits the evaluation of the effects of foods, drugs and other measures on the peripheral circulation simply by noting the changes in skin surface temperature. By observing

changes in the skin surface temperature of the body, particularly of that part which goes through the greatest range of change—the toe—it has been learned for example, that acetylsalicylic acid causes vasodilatation (chart 3). This may explain the value of this drug and of other similar acting drugs as antipyretics.<sup>23</sup> It may also explain the subjective relief that this drug appears to afford sufferers from chronic arthritis (in which condition endo-arterial changes in the blood vessels supplying the joint have been described), and those suffering from peripheral vascular disease.

The skin surface temperature reaction to tobacco has been described. In many individuals, smoking causes peripheral vasoconstriction as evidenced by a lowering of the surface temperature.<sup>24</sup>

Numerous studies have been made to show the effect of various physical therapeutic measures, such as the application of hot and cold baths, phototherapy, diathermy, and short wave currents.<sup>25</sup>

Alcohol causes a peripheral vasodilatation, as evidenced by the rise in skin surface temperature of the toe.<sup>26</sup> I observed that the rate of rise is faster after the drinking of whisky than of wine.

The ingestion of coffee as a rule causes a definite lowering of the skin surface temperature of the toe (chart 4). In my experiments the coffee was administered at a temperature of about 37.5 C (99.5 F).

Chart 5.—Effect of decaffeinated coffee (two cups) on a normal man aged 20. A decaffeinated coffee.

Decaffeinated coffee does not produce this change (chart 5). Caffeine, if administered hypodermically in the form of caffeine with sodium benzoate, or by mouth as caffeine citrate, causes a decided lowering of the skin surface temperature of the toe.

Thyroid increases the temperature of the skin surface of the extremities. Amyl nitrate does likewise, while pilocarpine decreases the temperature of the skin of the extremities.<sup>2</sup> The latter drug acts by stimulating the sweat glands, causing cooling by evaporation of the sweat without any preceding increase of the skin surface temperature.<sup>4a</sup>

The application of tincture of iodine and of mustard oil causes an initial lowering of the skin surface temperature at the site of application, followed by an increase of from 1 to 3 degrees C, lasting for from five to ten hours. If active hyperemia is produced by rubbing, the skin surface temperature rises according

to the strength of the stimulus, to the irritability of the individual and to the initial skin temperature<sup>4a</sup>

It may be of interest to evaluate the effect of other physical procedures and the effect of the ingestion of various food and drug substances on the peripheral circulation. While this objective evidence may not be the sole guide for the application of various therapeutic measures, it does give a definite standard by means of which these measures may be judged.

#### EFFECT OF ENVIRONMENTAL TEMPERATURE, HUMIDITY AND AIR MOTION

Observations of skin surface temperatures should be made in a temperature-controlled room, since the factors of room temperature, humidity and rate of air motion influence the temperature of the skin.

Systematic investigations on the relationship between room temperature and skin temperature have been made.<sup>27</sup> A positive correlation has been described between skin temperature and air temperature, the skin temperature increasing at the rate of 0.27 C per degree centigrade of room temperature, with a corresponding shift of 3 per cent of the total heat from radiation and convection to the latent heat of evaporation.<sup>28</sup> At the higher room temperatures, the physiologic action of sweating cools the skin.<sup>29</sup>

Other things being equal, heat loss is proportional to the square root of the velocity of air motion.<sup>30</sup>

#### INSTRUMENTS FOR MEASURING SKIN SURFACE TEMPERATURE

For measuring the temperature of the surface of the skin, the mercury thermometer is a relatively unsatisfactory instrument. Lacking other instruments for the purpose, however, it may be used, fitted with a wedge of cork to prevent loss of heat to the air,<sup>31</sup> or in a special shape with the lower portion flattened and bent at right angles to the stem. The mercury thermometer is objectionable because of its slowness in recording and because covering the surface distorts the temperature of the region.

The development of the thermocouple has simplified the study of skin surface temperatures. This instrument depends on the production of a minute electric current when the joined ends of two dissimilar metals are heated. For routine purposes I have found that one constructed with an automatically compensated cold junction is the most satisfactory. Resistance thermometers for the same purpose have been described, and also instruments for the measurement of the radiation of heat from the body's surface.<sup>32</sup>

With the exception of the studies made in recent years, but few investigations have been conducted during the century that has passed since the develop-

ment of an instrument suitable for the measuring of skin surface temperatures. It may well be that the relatively simple and accurate measuring instruments now available may help to usher in a period of intensive research, which should be fruitful in clarifying the diagnosis and the treatment of peripheral vascular as well as many other diseases.

471 Park Avenue

#### OBSERVATIONS ON THE TREATMENT OF CHRONIC ARTHRITIS WITH VITAMIN D

EMIL G. VRTIAK, MD

AND

ROSS S. LANG, MD

CHICAGO

Our interest in vitamin D therapy was stimulated by C. I. Reed, Ph.D., assistant professor of physiology, University of Illinois College of Medicine, who observed improvement of symptoms in two patients with arthritis whom he had treated for hay fever with vitamin D concentrate. One of these patients was a man aged 46 and the other, a woman aged 47. The former had suffered with chronic atrophic arthritis for seven months and the latter had suffered with it for fifteen years in addition to hay fever.

We have treated twenty cases of atrophic arthritis with daily doses of viosterol of from 150,000 to 250,000 U. S. P. X units of vitamin D.<sup>1</sup> Ten patients were men and ten were women. The youngest patient was 23 years of age and the oldest was 60. Fifty-five per cent of the patients were between 40 and 60 years of age.

Twelve, or 60 per cent, of the cases showed a varied degree of improvement, as shown in the accompanying table. Eight, or 40 per cent, did not improve.

The average age of the patients in the markedly improved group was 43 years, in the moderately improved, 43½ years, in the slightly improved, 49 years, of those in whom no improvement was noted, 41 years.

The average duration of the disease in the improved group was twelve years, in the moderately improved, two and three-fourths years, in the slightly improved, six years, in the not improved, ten years.

The average length of treatment in the improved group was three months, in the moderately improved group, ten months, in the slightly improved, seven and three-fourths months, in the not improved group, three and one-sixth months.

Of sixteen patients on whom blood counts had been made before treatment, five had red blood cell counts under 4,000,000. The hemoglobin in these five cases was 50, 57, 68, 75 and 90 per cent. Their average weight was 113 pounds (51 Kg.). Of these anemic and undernourished patients, four showed no improvement and one showed moderate improvement.

X-ray studies of the joints of the patients previous to treatment showed bone atrophy. Reexamination in five cases following treatment did not show any appreciable change in bone density.

From the Department of Medicine, Rush Medical College, University of Chicago.

1 The viosterol 850,000 units (U. S. P. X) of vitamin D per gram was supplied by Mead Johnson & Co.

Dreyer and Reed<sup>2</sup> found an excess of calcium deposits in most of the tissues in dogs following the administration of toxic doses of vitamin D. When administration was stopped and the animals were allowed to recover, the tissues showed calcium contents within the normal range.

Shelling and Jackson<sup>3</sup> found no excessive calcium deposits in tissues of human patients brought to autopsy after long periods of treatment with viosterol. They used relatively small doses.

Nausea developed in all our patients. In several, frequency of urination and nocturia developed.

#### SUMMARY AND CONCLUSION

Twenty patients with chronic atrophic arthritis were treated with massive doses of vitamin D.

Two patients showed marked improvement, six moderate improvement, four slight improvement and

#### Results of Treatment with Vitamin D in Twenty Cases

	Number	Ages	Duration of Disease, Years	Length of Treatment, Months	Blood Count

		28	2	1 1/2	4,240	6,800	0.80
		39	4	2	4,700		0.90
		39	7	2			
		44	8	2			
		47	1	3 1/2	3,500	13,000	0.75
		57	14	1 1/2	3,400	8,400	0.77
		60	30	6			
Average		41	10	3 1/6			
Total	20						

eight no improvement. These results were not unlike those obtained with a number of other methods of treatment or with methods used to produce only symptomatic relief.

Undernourished and anemic patients showed the least improvement.

Roentgenograms in five cases before and after treatment showed no change in bone density.

Nausea developed in all patients, in a few, frequency of urination and nocturia.

This series of cases is too small for an estimate to be made of the value of vitamin D in the treatment of chronic arthritis but is sufficient to indicate a conservative attitude toward this form of treatment.

## Clinical Notes, Suggestions and New Instruments

### POISONING BY CHICHESTER'S PILLS

Lyle Motley, M.D., and J. L. McGehee, M.D.  
Memphis, Tenn.

Though abortifacients are widely advertised and by inference extensively used, reports of serious toxic results from their use are rare.

#### REPORT OF CASE

**History.**—A white married woman, aged 22, entered the hospital with the complaint of epigastric pain and vomiting of two and a half days' duration. She had not voided urine for seventy-two hours.

**Examination.**—The patient was obviously ill. Her face was pale and somewhat puffy. General examination was negative except for diffuse tenderness of the abdomen, most marked in the lower part bilaterally. Pelvic examination showed blood coming from the cervix, which was gaping open, soft and edematous. The uterus was enlarged to the size of an eight weeks pregnancy. No masses were palpable on either side.

Blood examination revealed red cells 3,000,000, hemoglobin 6 Gm. per hundred cubic centimeters, leukocytes 18,600, polymorphonuclear neutrophils 94 per cent, lymphocytes 6 per cent. A catheter obtained 7 ounces (200 cc.) of dilute blood and it was stated by the patient and her husband that this was the first fluid that had left her bladder in seventy-two hours.

After examination the patient admitted having introduced the temporal part of horn rimmed driving glasses into her vagina and as far as she knew into the cervix. This was done several times the first seven days previously and the last time the night before the onset of symptoms two and a half days previously. On the last occasion she felt as though "something gave way" and, in view of the anuria and the large amount of blood obtained from the bladder, a cystoscopic examination was done by Dr. T. D. Moore considering the possibility that the bladder had been penetrated. The bladder was found intact and shortly afterward the laboratory reported a blood nonprotein nitrogen of 250 mg. per hundred cubic centimeters.

Further questioning brought forth the admission that she had taken twenty-eight Chichester pills and one box of Snyder's pills, the exact time of taking not being remembered by the patient, but within the past few days.

Apparently the uterus was draining freely, the temperature and leukocytosis were not excessive and, except for cleansing douches, no local measures were used, the outcome of the obvious severe nephritis being awaited.

**Subsequent Course.**—Mild stupor appeared shortly after the patient was admitted and cleared to a large extent within forty-eight hours. The temperature did not go above 99.5 F. and after the first seven days did not go above normal. A blood transfusion was given and adequate attention to the physiologic needs regarding water balance, calories and minerals being given intravenously. The leukocytes never went above the original figure and the red cells gradually rose to 4,500,000, with hemoglobin of 12 Gm. per hundred cubic centimeters. The blood nonprotein nitrogen rose to 444 mg. with creatinine as high as 10.22 mg. per hundred cubic centimeters. At this time spontaneous bleeding from the gums appeared and investigation of the blood showed no alteration in coagulation factors. Thirty cc. of urine was obtained by catheter the first twenty-four hours, the specimen being quite bloody but not as much so as the original. The urinary output gradually increased, even while the blood nitrogen was rising, and fourteen days after admission amounted to 1080 cc. with a fluid intake of 1,500 cc. on the day that the blood nitrogen was the highest. This urine showed a specific gravity of 1.008 a faint trace of albumin, numerous pus cells and from 15 to 20 red cells to the high power field. At no time did the blood pressure exceed 112 systolic 70 diastolic. The ekg. remained normal at all times and no definite edema ever appeared. Her mental condition cleared rapidly after the first thirty-six hours, even in the face of a rising blood nitrogen.

From the Departments of Medicine and Surgery, University of Tennessee College of Medicine.

Nausea was the only symptom complained of, and the patient was unable to retain anything in her stomach for more than an hour after ingestion.

About the time the urine output became normal, the nitrogen began to fall rapidly and within two weeks was at a normal figure. All symptoms had disappeared and the patient was considered clinically well. She was seen in the office a month after discharge and was still apparently normal.

Pelvic examinations showed no reason for surgical intervention at any time and when the patient left the hospital the uterus was undergoing involution and no discharge was present.

#### COMMENT

The Bureau of Investigation of the American Medical Association states that Chichester's Diamond Brand Pills contain as the chief medicinal constituents aloes and iron sulfate and that tests for the presence of black hellebore, tansy, pennyroyal, savin and certain other reputed abortifacients resulted negatively in each case. Essentially the same results were obtained by a government chemist in connection with a suit involving interstate shipment of the pills.<sup>1</sup>

In discussing the action on the kidney of the reputed abortifacients, Sollmann<sup>2</sup> states that aloes and the pentoside allox produce tubular nephritis with increased or diminished urine containing proteins, leukocytes, casts and blood. In the case here reported, it was evidently the action of aloes that produced the renal lesion.

In response to inquiry, the Bureau of Investigation writes that the Snyder Products Company of Chicago markets a product under the name of "S P New Discovery Relief Compound for Unnatural Delayed Periods." The bureau did not know the composition of the pills, as inquiries have been too few to warrant investigation and analysis. It is assumed that they contain some combination of aloes, tansy, savin, arbor vitae, pennyroyal or cottonroot bark, as they are the substances commonly supposed to have abortifacient properties.

In discussing other supposed abortifacients, Sollmann states that arbor vitae and tansy are oils similar to turpentine but more toxic. Poisoning has occurred from their use as abortifacients, with hematuria. Six drops of these substances is said to have produced toxic effects. In no book on pharmacology is mention made of the effects of pennyroyal on the kidneys.

While tansy is popularly supposed to have abortifacient properties, no mention is made of this in any reference, but the active constituent is thugon ( $C_{10}H_{16}O$ ), as with arbor vitae, and has the same toxic effect. Cottonroot bark contains various resins but in no reference is there any mention of action on the kidneys.

It must be assumed that if Snyder's pills played any part in the toxic nephritis in this case in addition to the aloes in Chichester's pills they must contain aloes, arbor vitae, tansy or a combination of them.

#### DIPHTHERITIC MENINGITIS. REPORT OF A CASE AND REVIEW OF THE LITERATURE

F G CARLSON, M.D. AND H W MORGAN, M.D.  
MASON CITY, IOWA

The extreme rarity of meningitis with true diphtheria bacilli as the etiologic agent leads us to believe that the occurrence of such a case is worthy of a report. A very careful search of all the available English literature fails to reveal any similar case. There are, however, a number of cases in the English literature in which a diphtheroid organism or an organism resembling the diphtheria bacillus in some particulars has been reported.

Miller and Lyon<sup>1</sup> reported a threadlike diphtheroid organism as a causative agent in meningitis in an infant.

Kessel and Romanoff<sup>2</sup> of New York reported a general infection with the diphtheroid bacillus complicated by a diph-

theroid meningitis. A blood stream infection was present in their case.

Dr. Dick<sup>3</sup> of Chicago reported a case of meningitis due to a diphtheroid organism which showed no polar bodies and was not pathogenic to guinea-pigs except on intravenous inoculation.

One case of diphtheritic meningitis was reported by Moritz<sup>4</sup> in the French literature, in which he found both the meningococcus and the Klebs-Loeffler bacillus in the spinal fluid. He gives no record of a virulence test being made on the Klebs-Loeffler bacillus. A number of men have reported on the changes in the spinal fluid of diphtheritic paralysis and all agree that the organisms are never found in the spinal fluid in this condition.

In the German literature, four cases of meningitis with the Klebs-Loeffler organism as the proved etiologic agent were found. The first of these was described by von Stirling and reported by Pockels<sup>5</sup> in a child suffering with a mastoid infection. A brain abscess developed from which a pure culture of Klebs-Loeffler bacilli was obtained.

Pockels<sup>5</sup> reported a case in which a 7½ year old child showed symptoms of meningitis. On culture of the spinal fluid, both the streptococcus and the diphtheria bacillus were obtained.

Fuchs<sup>6</sup> reported a case in a woman, aged 38, in which a culture of the spinal fluid showed a diphtheria bacillus. The patient recovered following the use of diphtheria antitoxin.

Glaser<sup>7</sup> in 1917 reported a case of true diphtheritic meningitis in a soldier in whom the bacteriologic examination revealed Klebs-Loeffler bacilli and the patient recovered following the use of antitoxin.

Reiche<sup>8</sup> in 1914 reported a number of cases of meningitis complicating diphtheria; however, in all his cases the meningitis was due to some organism other than the diphtheria bacillus.

The following case of meningitis due to the Klebs-Loeffler bacillus occurred in our hospital recently.

#### REPORT OF CASE

A white boy aged 2½ years was admitted to St. Joseph's Mercy Hospital, Dec. 5, 1934. The parents stated at the time of admission that the patient had been sick for approximately ten days prior to entering the hospital. He was seen by a physician in a neighboring community, and a diagnosis of bilateral otitis media was made and paracentesis was done. The patient improved following this procedure. The ears, however, stopped draining and were reopened after two or three days by the same physician, at which time he noted signs of a meningitis and urged hospitalization. This was refused by the parents, and the patient was not under medical supervision for approximately three days, at which time a second physician was called and the patient was referred to the hospital. On admission an examination of the ears showed a small amount of a dried exudate in one auditory canal, with evidence of previous paracentesis in both drums but no evidence of bulging or involvement of the drum at the time of examination. Roentgen examination of the mastoids at this time showed no destruction of mastoid cells. A spinal puncture was done. The fluid was cloudy and under increased pressure. The globulin was increased. There were approximately 20,000 cells per cubic millimeter and smears showed many organisms that morphologically appeared to be Klebs-Loeffler bacilli. Examination of the throat showed it to be slightly red, but there was no evidence of a membrane in the nose, pharynx or larynx. However, a culture of the throat was positive for Klebs-Loeffler bacilli. The patient received 5,000 units of diphtheria antitoxin intramuscularly and the following day 8,000 units of antitoxin was administered through a cisternal puncture. Examination of the spinal fluid obtained at this time again showed the same organism. A third injection of 10,000 units, intramuscularly, was given. Repeated spinal punctures were

8. Reiche F. Meningitis bei Diphtherie. Ztschr. f. Kinderh. 11: 452-459 1914.

1. Notice of Judgment 15052 Southern District of New York issued in December 1927.

2. Sollmann Torald. Manual of Pharmacology Philadelphia W. B. Saunders Company 1928.

1. Miller M. K. and Lyon M. W. Meningitis Due to a Threadlike Diphtheroid Organism in an Infant. Am. J. M. Sc. 162: 893 (Oct.) 1921.

2. Kessel Leo and Romanoff Alfred. General Infection with Diphtheroid Bacillus Complicated by Diphtheroid Meningitis. J. A. M. A. 94: 1647-1648 (May 24) 1930.

done until the fluid became so thick that it would not run from a No 18 needle. Following this, cisternal punctures were done for relief of pressure.

The physical examination, other than that just given, was negative except for a rapid pulse, a few moist rales in the chest, positive Kernig and Babinski reflexes, and a stiff neck.

The temperature remained high and the patient failed gradually and died December 14, after being in the hospital nine days.

Laboratory work, other than on the spinal fluid, showed a few erythrocytes and leukocytes in the urine and 1 plus albumin. The red blood cell count was 3,680,000, the white blood cell count was 34,400, the hemoglobin 70 per cent, polymorphonuclear leukocytes 75 per cent, lymphocytes 20 per cent, monocytes 3 per cent, myelocytes 2 per cent and a shift to the left (Schilling) of 25 per cent.

The organism grew in pure culture. A virulence test was run and the organism found to be a virulent diphtheria bacillus.

On the day following admission of the patient to the hospital a younger child in the family was seen with a temperature of 104 F and a positive smear and culture of the throat, although no membrane was present in this child. He received antitoxin and was referred to the care of his home physician, who reported that the next day the temperature returned to normal and remained normal.

Autopsy was negative except for a diffuse purulent meningitis covering the entire brain and the spinal cord, and a bilateral otitis media with mastoiditis. There was little destruction of bone present. There was no evidence of myocardial damage. Microscopic sections of the brain showed only superficial involvement, with relatively little penetration of the infectious process.

#### SUMMARY

In a case of fatal meningitis with Klebs-Loeffler bacilli as the causative agent guinea-pig inoculation showed the organisms to be a virulent strain.

No similar cases could be found in the English literature.

The German literature contained four cases.

The case reported developed following otitis media and mastoiditis.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary

#### LACTOBACILLUS ACIDOPHILUS MILK (TOWT) OMITTED FROM N N R

Lactobacillus Acidophilus Milk (Towt), prepared by Towt-Nolan Laboratory, was accepted by the Council in 1927 as meeting the conditions prescribed for similar lactic acid producing preparations.

At the expiration of the period for which it was accepted the Council examined the data submitted by the firm as evidence of its eligibility for continued inclusion. A number of objections to labels, circulars and miscellaneous advertising matter were reported. The firm was informed of these objections and further informed that the product would be reaccepted if the objections were met. A reply was received by the Council in which the firm expressed its intention to cooperate at all times but asked that the Council grant a period of six months in which to use up a supply of material that was on hand. The Council acceded to the firm's request for a six months period. When this period had expired the firm was asked to submit the necessary revised material. No reply was received to this request and two reminders were likewise ignored. Since the firm has not lived up to its agreement to cooperate, the Council has no alternative but to omit the product from New and Non-official Remedies.

The Council therefore voted to omit Lactobacillus Acidophilus Milk (Towt) from New and Nonofficial Remedies because the manufacturer failed to submit evidence of its continued acceptability.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**BOTULINUS ANTITOXIN**—An antitoxic serum prepared by immunizing animals against two or more strains of the toxin of *Clostridium botulinum*.

**Actions and Uses**—For prophylaxis and treatment of botulism. Jensen-Salsbery Laboratories, Inc., Kansas City, Mo.

**Botulinus Antitoxin (Human) Jensen Salsbery**—This antitoxin is prepared by the hyperimmunization of horses and cattle by continued and progressively increasing doses of botulinus toxin. It is prepared against two types of the toxin, namely A and B. Each type is prepared in separate animals and the commercial product is prepared by mixing given quantities of each type so that each marketed package will contain 2,000 units each of type A and type B antitoxin, the unit of each being that established and distributed by the National Institute of Health. The animals are bled at specified intervals and the same technique is used in preparing the final product as is required by the National Institute of Health in the preparation of the antitoxins for which standards have been established. The product is not concentrated but consists of the whole serum as it is derived from the defibrinated blood by process of centrifugation and Berkefeld filtration. The preservative consists of a mixture of equal parts of refined tricresol and ether so that the final volume is 0.8 per cent of the combined preservative. It is marketed in packages of one vial containing 2,000 units each of type A and type B botulinus antitoxin.

**Dosage**—Prophylactic subcutaneous injections of at least 2,000 units of bivalent antitoxin curative intravenous injection of at least 10,000 units of the bivalent antitoxin repeated as the nature of the case indicates.

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

#### HEINZ BRAND STRAINED MIXED GREENS

**Manufacturer**—H. J. Heinz Company, Pittsburgh

**Description**—Canned mixture of strained kale, green lettuce and green asparagus retaining in high degree the natural vitamins and minerals.

**Manufacture**—Fresh kale, green lettuce and green asparagus are trimmed and washed. Equal quantities are mixed, cooked and strained in the absence of air (coarse fibrous material is removed), vacuumized to remove occluded air and filled into enamel lined cans, which are sealed under vacuum and processed.

**Analysis** (submitted by manufacturer) —

	per cent
Moisture	92.7
Total solids	7.3

**Calories**—0.2 per gram, 6 per ounce

**Vitamins**—Vitamin biologic assay shows 380 Sherman units (530 international units) of vitamin A per ounce, 13 Sherman units of vitamin B per ounce, 14 Sherman-Bourquin units of vitamin G per ounce.

**Chemical** analysis shows 123 international units of vitamin C per ounce.

**Claims of Manufacturer**—For table use, but especially intended for infants, children and convalescents.

- 1 FAULTLESS BRAND TOMATO JUICE
- 2 JACK SPRAT BRAND TOMATO JUICE
- 3 MARSHALL BRAND TOMATO JUICE
- 4 UNCLE WILLIAM BRAND TOMATO JUICE

*Distributors*—2 Jack Sprat Foods, Inc., Marshalltown, Iowa  
3 Marshall Food Products Company, Marshalltown, Iowa 1  
and 4 Marshall Canning Company, Marshalltown, Iowa

*Manufacturer*—Marshall Canning Company, Marshalltown, Iowa

*Description*—Tomato juice seasoned with salt retaining in high degree the natural mineral and vitamin values

*Manufacture*—Specially selected ripe tomatoes, free from cracks or blemishes, are thoroughly cleaned, mechanically broken, and heated to 77 C. The juice is mechanically separated from cores, stems, skins and seeds in a steam atmosphere, slightly seasoned with salt, heated under vacuum, filled into cans, sealed and heat processed

<i>Analysis</i> (submitted by manufacturer)	per cent
Moisture	94.1

Acidity as citric acid	0.4

*Calories*—0.2 per gram 6 per ounce

*Vitamins*—The process avoids admixture of air with juice at all stages and consequently is considered efficient to retain vitamin C in high degree

*Claims of Manufacturer*—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C. For infant feeding and general table use

#### LOEFLUND'S MALT SOUP STOCK

*Distributor*—Schieffelin & Company, New York

*Manufacturer*—Ed Loefflund & Company, Grunbach near Stuttgart, Germany

*Description*—Concentrated malt extract with added potassium carbonate and bicarbonate

*Manufacture*—Barley malt mash is maintained at an appropriate temperature until the enzymes have converted the starch to a definite ratio of maltose and dextrans, the solution is filtered, the filtrate admixed with 11 per cent potassium carbonate and bicarbonate (1.08), condensed under reduced pressure to the desired concentration, and canned

<i>Analysis</i> (submitted by manufacturer)	per cent

Protein (N $\times$ 6.25)	4.5
Reducing sugars as maltose	57.58
Dextrans (by difference)	12.13

Only small amount of diastase is retained

*Calories*—3.0 per gram 85 per ounce

*Claims of Manufacturer*—For use in infant feeding under the direction of a physician

- 1 DOLE BRAND HAWAIIAN PINEAPPLE ROYAL SPEARS
- 2 DOLE BRAND HAWAIIAN PINEAPPLE GEMS

*Manufacturer*—Hawaiian Pineapple Company, San Francisco

*Description*—1 Canned, peeled and cored Hawaiian pineapple cut into longitudinal sections and packed in pineapple juice with added cane sugar

2 Canned peeled and cored Hawaiian pineapple, cut in thick segments and packed in pineapple juice with added cane sugar

*Manufacture*—1 Same as Dole Hawaiian pineapple products (THE JOURNAL April 8 1933 p 1106) except that the fruit is cut into longitudinal sections ("spears" or "fingers")

2 Same as Dole Hawaiian pineapple products (THE JOURNAL, April 8, 1933, p 1106) except that the fruit is cut into 1 to 1½ inch slices, which are then divided into segments

<i>Analysis</i> (submitted by manufacturer) —	Spears per cent	Gems per cent
Moisture	75.9	73.9
Total solids	24.1	26.1
Ash	0.4	0.4

Carbohydrates other than crude fiber (by difference)	23.0	25.0
Titrateable acidity as citric acid	0.7	0.6

*Calories*—0.9 per gram 26 per ounce

*Vitamins*—Biologic assay shows canned pineapple to contain vitamin A and to be a good source of vitamins B and C. Practically equivalent to the fresh fruit in A and B slightly inferior in C

*Claims of Manufacturer*—The canned product is practically equivalent to the fresh fruit in nutritional values (vitamin C slightly reduced). Fancy quality

#### SUNSHINE BRAND EVAPORATED MILK

*Manufacturer*—Litchfield Creamery Company, Litchfield, Ill

*Description*—Unsweetened sterilized, evaporated milk

*Manufacture*—Milk received from company inspected farms is tested on arrival at the plant for acidity, sediment and odor. The milk is filtered, preheated to 100 C, evaporated, homogenized, cooled to from 2 to 4 C, automatically canned and sealed, processed at 117 C for from eighteen to twenty minutes, and cooled

<i>Analysis</i> (submitted by manufacturer) —	per cent
Moisture	73.9
Total solids	26.1
Ash	1.5
Fat (ether extract)	7.8
Protein (N $\times$ 6.38)	7.5
Lactose (by difference)	9.2

*Calories*—1.4 per gram 40 per ounce

*Claims of Manufacturer*—See announcement on the advertising of the Evaporated Milk Association (THE JOURNAL, Dec 19, 1931, p 1890)

#### CELLU BRAND LITTLE KERNEL CORN WATER PACKED

*Distributor*—Chicago Dietetic Supply House Inc, Chicago

*Packer*—L. H. Schlecht, Rossville, Ill

*Description*—Canned corn (cream style) packed in water

*Manufacture*—Selected ears of corn of the proper degree of maturity are trimmed, brushed to remove silk and washed. The kernels are cut from the cob, mechanically treated for removal of bits of cob and silk, mixed with water and preheated to disrupt starch granules and develop creamy consistency. The corn is then filled into cans, sealed and processed

Illustrated booklet prepared by Esmond Gundlach & Co., advertising agency, Cincinnati, for distribution by producers of accepted homogenized milks explanatory of the physical changes and more rapid digestibility of milk resulting from homogenization

# REPORTS OF OFFICERS

**NOTE**—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion—Ed

## REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association

The following report of the Secretary is respectfully submitted

### MEMBERSHIP

Since the annual session of the Association is being held one month earlier than is usual, the report pertaining to membership and Fellowship is based on enrollment on March 1, 1936 rather than on April 1

The number of members enrolled on March 1 1936, was 101,754 This represents an increase of 2,218 over the number of members reported as of April 1 1935 at the Atlantic City session

### FELLOWSHIP

The number of Fellows of the Association as shown by the official roster, on March 1 1936, was 62,997 an increase of 1,591 over the number reported as of April 1 1935

An accompanying table indicates the number of counties in each state and territory the number of component societies as shown by the records in the Secretary's office the number of members enrolled at the time the count was made for the purposes of this table and the number of Fellows including Honorary Fellows and commissioned officers of government medical services

### ORGANIZATIONAL ACTIVITIES

From information secured through correspondence with secretaries and other officers of constituent associations and component societies and from information otherwise received it is clearly apparent that constant progress is being made in most of the states in strengthening the machinery of medical organization and in extending the influence of state and county medical societies In several states greater care is being exercised in the selection and admission of members Much closer contact is being maintained with organized groups among the lay public that have concerned themselves with medical and public health affairs It seems quite apparent that the officers and members of many societies are carefully studying conditions existing within their own jurisdictions with a view to enhancing the service that can be rendered to their own members and to the public Even so there is still room for improvement in many places, because there are still too many county medical societies that are comparatively inactive and some that are practically dormant

### ANNUAL CONFERENCE OF SECRETARIES OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

The Annual Conference of Secretaries of Constituent State Medical Associations was held in Chicago in November 1935 with a fine attendance It is gratifying to note that the number of officers of state medical associations other than secretaries and editors who attend the Conference is increasing with each succeeding year, and it is heartening indeed to observe the fine spirit of mutual helpfulness exhibited by the members of the Conference The discussions that take place at these conferences are free and frank and are characterized by friendly criticisms and suggestions which are intended to be constructive and helpful

### FIELD WORK

The elective officers of the American Medical Association and individual members of the Board of Trustees and of other official bodies, the Editor of THE JOURNAL the Secretary and General Manager, and directing heads of the Association's councils, bureaus and departments have visited many medical societies in practically all parts of the United States during the

last year Representatives of the Association have appeared before a greater number of lay audiences than ever before The Editor of THE JOURNAL the Director of the Bureau of Health and Public Instruction and the Director of the Bureau of Medical Economics have appeared as speakers on a number

of radio programs and have thus reached audiences that are said to have included millions of persons

A number of constituent state medical associations have largely increased their field activities and have inaugurated splendid educational programs In a few states the presidents and secretaries of the state medical associations have visited

every component county medical society within their respective states. Reports received from official sources indicate that the councils of the constituent associations, or the boards of trustees, which in some states correspond to the councils, are giving more zealous attention to their official duties than ever before.

#### RESOLUTIONS FROM CALIFORNIA MEDICAL ASSOCIATION

The following resolutions were transmitted by the secretary of the California Medical Association with the request that they be included in the Handbook of the House of Delegates and printed in the AMERICAN MEDICAL ASSOCIATION BULLETIN.

Under instructions of the Council of the California Medical Association, the California Medical Association delegates to the 1936 Kansas City Session are directed to introduce the following resolution in the American Medical Association House of Delegates:

WHEREAS Certain organized lay groups in this country are endeavoring to arrange for the provision of diagnostic medical service along with and as part of hospital services and

WHEREAS The provision of such diagnostic medical service will inevitably foster fundamental changes in the practice of medicine and

WHEREAS Such changes in the practice of medicine may well result in deterioration of our present medical standards and especially in deterioration in the quality of medical care furnished to hospital patients now therefore be it

Resolved That it is the official policy of the House of Delegates of the American Medical Association that it disapproves of the division of any branch of medicine into technical and professional portions and be it further

Resolved That copies of this resolution shall be brought to the attention of the American Hospital Association and its affiliated groups to the end that existing arrangements permitting division in medical practice be terminated as speedily as possible

#### MEMBERSHIP JURISDICTION

It is important for various reasons that the jurisdiction of component societies and constituent associations with respect to membership should be clearly defined and definitely maintained. In most if not all states, provision is made whereby physicians residing in one county may become members of the medical society of an adjoining county provided the society of the county in which they reside and practice will waive jurisdiction. This is undoubtedly a wise provision, designed to serve the convenience of a comparatively large number of physicians who reside near county lines, and no doubt tends to bring into membership qualified physicians who otherwise might withhold their affiliation.

There are many physicians located near state lines, and there seems to be an increasing tendency for such physicians to maintain membership in the component county medical societies of states other than those in which they reside and practice. There are reasons why it is just as important for the jurisdiction of a constituent state medical association over physicians within its own territory to be as definitely fixed as the jurisdiction of the component county medical society. It is therefore respectfully suggested that the House of Delegates at this session consider the advisability of formulating suggestions, to be offered to the constituent associations, to the effect that physicians residing near state lines may be given the privilege of affiliating themselves with the component societies of immediately adjacent counties in other states. Such an arrangement would involve definite agreements between the constituent state medical associations of adjoining states.

The Secretary again makes most grateful acknowledgment of the many considerate kindnesses that have been shown him by the members and officers of official bodies of the Association by the officers of constituent state medical associations and component county medical societies, by members of this House of Delegates, and by a large number of the individual members of the Association in all parts of the country.

Respectfully submitted OLIN WEST, Secretary

#### REPORT OF THE BOARD OF TRUSTEES

*To the Members of the House of Delegates of the American Medical Association*

During each of the last ten years there has been a very constant increase in the work that the American Medical Association has been called on to do and a very earnest effort has been made to expand the needed facilities within the bounds of reason and safety. Not only has the amount of work grown

greater year after year, but the scope of the Association's activities has been greatly extended. Whenever any new facility has been provided, new demands have been created, until in 1935 an entirely new mark measuring the amount of work done in the Association's offices was established.

It became necessary during the year to increase the working personnel until, at the time this report was prepared, there were more than 550 persons in the Association's employ.

#### The Journal of the American Medical Association

The increasing circulation of THE JOURNAL, the innumerable references to its columns in medical and lay periodicals and in newspapers throughout the world, and the great number of letters received from subscribers testify to the almost universal appreciation of this publication. Several series of special articles, notably those on glandular therapy and on the therapy of the Cook County Hospital, have attracted special attention. Arrangements are being made to republish the first series in several foreign languages. The department of questions and answers has gradually assumed increasing significance as a source of reference for the general practitioner. Many comments indicate that its practical value is generally realized. THE JOURNAL continues to serve as the voice of the organized medical profession of the United States, reflecting not only scientific advancement but also the interest of the profession in medical education and medical economics.

Tables 1 and 2 indicate the approximate count of Fellows and subscribers carried on the mailing list of THE JOURNAL, showing the gain or loss of Fellows and subscribers and the number of physicians receiving THE JOURNAL in each state.

The average number of copies of THE JOURNAL printed weekly during the year 1935 was 88,843. The net paid circulation Dec 31, 1935, was 89,179, an increase of 4,344 over the net paid circulation on a similar date in the previous year.

#### Summary

*The Journal of the American Medical Association has been maintained at the high standard of recent years and is developing new features of practical value pointed toward the interest of the general practitioner.*

*The paid circulation, Dec 31, 1935, was larger by 4,344 than on the same date in 1934.*

#### Special Journals

During 1935 the special periodicals were maintained at the usual scientific standard which they have held since their inception. The Association now publishes special periodicals in the field of internal medicine, diseases of children, otolaryngology, ophthalmology, pathology, neurology and psychiatry, dermatology and syphilology, and surgery. These publications are issued primarily with the view to advancing the sciences with which they are concerned. They have been everywhere recognized as equal to the very best in their fields published anywhere else in the world.

The special journals of the American Medical Association are not published in the interests of any single specialistic organization but are planned primarily with a view to the promotion of the science rather than of the individuals or the groups interested in that science. Recently other periodicals have been issued by commercial publishing organizations which have become the special organs of certain groups organized within some of the specialties. This has served to diminish to some extent the circulation of our own publications, since those who join the special organizations are compelled to subscribe to the privately published periodical as a part of their membership. Members of the Association who devote themselves primarily to specialties should realize the independent nature of the publications issued by the Association and should realize also that the continuance of such publications depends on the support given to them by those who practice these specialties. The special periodicals are not published with any idea of commercial gain, in fact they have regularly shown a loss as a group since the time when they were first established.

During the year, requests have been received by the Board of Trustees for the establishment of additional periodicals in special fields. The decision as to whether or not the Associa-

tion can still further extend its efforts in this direction will naturally depend on the support which develops from the medical profession as an indication of the extent to which the periodicals are desired

With the beginning of 1935 the ARCHIVES OF INTERNAL MEDICINE established the policy of publishing in each issue a

competent review of the advancement of knowledge in some special field of internal medicine. These reviews have been received with enthusiasm and commendation throughout the world. In fact, the project has been so successful that appeals are already being made for the publication of such material in independent book form. Encouraged by this reception the editors of the ARCHIVES OF INTERNAL MEDICINE have made plans to continue the reviews as a permanent feature of the ARCHIVES.

The circulation of the special scientific journals has been somewhat unfavorably affected by the economic situation, although the total circulation of this group of publications was increased by nearly 1,000 in 1935.

Only two of the special journals the ARCHIVES OF OTOLARYNGOLOGY and the ARCHIVES OF OPHTHALMOLOGY produced incomes in excess of the cost of publication. The cost of publication of the entire group in excess of income received was \$28,004.70.

### Summary

The special journals have been continued on their usual high plane.

The Board of Trustees views with some alarm the establishment of commercially published periodicals, in some special fields, which become the official organs of special organizations involving a compulsory subscription and thereby detracting from the subscribers and incomes of our own periodicals, which are not published in the interests of any special groups.

The Board of Trustees is being importuned for the publication of additional special periodicals, and the matter is being given consideration.

There was a small gain in the total circulation of the special journals. The loss sustained in 1935 was \$28,004.70.

### Hygeia

Increasing circulation and innumerable quotations from HYGEIA in newspapers and in other periodicals testify to the manner in which HYGEIA is reaching a vast audience. Hardly a day passes in which letters are not received from magazines devoted to digests of important literature, magazines in the field of education and periodicals devoted to industry and labor,

\* This table gives the number of physicians (based on the Thirteenth Edition of the American Medical Directory) in the United States the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army and Navy are not included.

requesting the right to abstract or reprint articles from HYGEIA. Its dramatization of health is being regularly used in many schools. The illustrations have been kept at a high standard and the content appeals to many different interests in the health field. The HYGEIA editorials have been designed to give to the public the point of view of the medical profes-

sion in relation to sociological, economic and scientific subjects. Commendations of the American Medical Association for this venture come from many sources, including individual subscribers, laymen, dentists, nurses, teachers, health officers and practicing physicians.

Even though the total circulation was well maintained during the year and was considerably increased in the last month or two, the income received was less than the cost of publication by the sum of \$31,311.29. The loss sustained was largely due to the cost of promoting circulation and to expenditures made for its improvement. The advertising income in 1935 was only slightly in excess of the income from the same source in 1934. The total number of subscriptions at the end of the year was 86,745.

#### Summary

*The numerous commendations and the increasing use of Hygeia in schools and as a source of public health information for many publications indicate that it is serving well the purpose for which it was established by the House of Delegates.*

*The cost of publication in 1935 was considerably larger than income received.*

#### The Library

The library continues to render a maximum of service to the medical profession directly and through its contributions to the publication department of the Association.

During 1935, 9,854 periodicals were lent to physicians on individual requests, 3,113 package libraries containing reprints and periodicals were sent to physicians, the majority of the requests coming from Illinois, New York and Pennsylvania, three states in which medical libraries are easily available to the membership. Thus Illinois made 375 requests, notwithstanding that it has seventeen medical libraries. New York sent 218 requests, notwithstanding its thirty-four medical libraries, and Pennsylvania sent 195 requests notwithstanding its twenty-four medical libraries. Next in order came Indiana with 156 requests but with only three libraries, Ohio 141 requests with eleven libraries, and Michigan 133 requests with only eight libraries. These figures should indicate the necessity of maintaining the package library service on the high plane which it has occupied from the beginning.

In addition to these services, the library answered 4,500 bibliographic questions. As usual the indexes to THE JOURNAL and to some of the books published by the Association were made in the Library. Although the library of the Association is planned primarily for service to the membership throughout the country, service was given directly to approximately 1,000 visitors during the year.

The QUARTERLY CUMULATIVE INDEX MEDICUS has now reached a point at which it is recognized throughout the world as the most significant publication in the medical bibliographic field. Its importance increases as other indexes, such as the Index Catalogue of the Library of the Surgeon General's Office, have become less available.

The time lag between the receipt of the foreign literature and its inclusion in the INDEX has been cut down to four weeks.

During the year the employees' library showed a circulation of 5,737 books with an average daily circulation of twenty-four. 135 of the 550 employees of the Association availing themselves of this service.

#### Summary

*The library has extended the scope of the periodical loans and the package library service, has maintained the Quarterly Cumulative Index Medicus at a high standard of efficiency and has rendered increasing service to the headquarters office in the preparation of indexes and of reference work for the various departments.*

#### Quarterly Cumulative Index Medicus

The circulation of the QUARTERLY CUMULATIVE INDEX MEDICUS, one of the most important of all publications in the field of medicine and one of the greatest contributions made by the American Medical Association for the promotion of medical science, is largely confined to libraries. A copy of this publi-

cation in a library may be used by many individuals. The number of personal subscriptions is small. Of the total circulation of the INDEX MEDICUS, 616 copies go to foreign countries.

The cost of publication of the QUARTERLY CUMULATIVE INDEX MEDICUS in 1935 amounted to the sum of \$44,439.84 over the amount of income received.

#### American Medical Directory

The Fourteenth Edition of the American Medical Directory at the time this report is written is being made ready for the press. It has been necessary to make a large number of changes in addresses as well as in the items of information concerning medical societies and institutions.

The total number of copies of the Thirteenth Edition of the Directory sold up to Dec. 31, 1935, was 8,280.

It is too early to hazard any prediction as to the probable cost of the Fourteenth Edition of the American Medical Directory.

#### Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau represents thirty-two of the thirty-four journals of constituent state medical associations.

Commissions earned in 1935 amounted to \$26,224.26, as compared with \$21,247.06 in 1934. The sum of \$9,000 was remitted to the state journals concerned, \$3,000 more than was distributed to them in 1934. These remittances were distributed to the state journals in proportion to the total amount of advertising secured for each of them.

#### Summary

*Thirty-two of the thirty-four journals of constituent state medical associations are represented in the Cooperative Medical Advertising Bureau. From the earnings of the Bureau the sum of \$9,000 was distributed among these journals in amounts proportionate to the total amount of advertising secured for each journal.*

#### Building and Equipment

For several years the need for a larger and better arranged building has been very apparent, and this fact has been brought to the attention of the House of Delegates in official reports previously submitted by the Board of Trustees. Careful consideration was given to the proposal that an entirely new building should be erected, but largely because of the unsettled economic conditions prevailing it was finally decided to enlarge the present building by the addition of two stories and to make alterations on several of the floors of the existing structure. When the building that has been used for several years was constructed, the plans provided for two additional stories. The Board of Trustees was advised by competent architects and engineers that, because of the splendid condition of the building and because of the comparatively large investment which it represented, it would perhaps be more desirable to erect two additional stories and to alter existing floors rather than to undertake the erection of an entirely new building. Another important reason which led to the decision to enlarge the present building was found in the fact that some of the bonds held by the Association had matured and were retired while others were called and replaced by securities bearing lower interest rates, and that it was found to be rather difficult to invest the proceeds of bonds that had matured or had been called without paying high premiums for new securities. The time seemed to be propitious for enlargement and improvement of the Association's housing facilities.

With the enlargement and alterations that are now being made it will be possible for departments closely allied to be brought together on one floor. This is particularly true of the Editorial Department, which is now scattered over three floors. In the future, this department together with the library will be located on the eighth floor of the enlarged building. It will be possible to have the offices of the Council on Pharmacy and Chemistry, the Council on Physical Therapy, the Committee on Foods and the Chemical Laboratory brought together on one floor and thus to correlate the work of these departments more closely than could be done in the past. Additional room will be made for other departments which have been forced to

occupy rather cramped quarters, and it is the hope and belief of the Board of Trustees that because of greater room that will be provided and more convenient arrangements that can be made the constantly increasing work that the Association is called on to do can be performed with greater facility and efficiency.

New elevators and new machinery for handling paper in the printing department will be included in the improvements. The brick walls on the Dearborn Street front and on the Grand Avenue side of the building have been replaced with stone and the building has thereby been much beautified.

An assembly hall, which will be located on the top of the building, will make it possible for meetings of the House of Delegates and for the Annual Conference of Secretaries of Constituent State Medical Associations as well as for other important meetings to be held at the Association headquarters.

It is expected that the building will be completed within a short time.

Because of constantly increasing demands on the printing department, it has become necessary to install additional linotype machines, to replace some presses and other machinery that is now outworn, to enlarge the stereotype room and to add to the equipment of that department.

The total outlay required for altering and enlarging the building and for providing new equipment and machinery will approximate \$425,000.

#### Summary

*Two stories have been added to the Association's building and alterations made on the lower floors.*

*An assembly room will be provided.*

*Enlargement of facilities in the mechanical departments is being made and outworn machinery is being replaced.*

*The offices of correlated departments will be brought together and more space will be available for offices that have heretofore been crowded.*

#### Council on Pharmacy and Chemistry

At the close of 1935 the Council completed its thirtieth year of service for the better interests of medicine. In a report of the Council fifteen years ago the following statements were made:

It was a genuine disappointment to the Council to find (since its organization in 1905) that some large and old established firms were not only unwilling to cooperate with the Council but in many instances exhibited a definite antagonism to the Council's work. The antagonism of certain pharmaceutical houses is therefore a matter of cold blooded business policy. When the medical profession as a unit will support the Council on Pharmacy and Chemistry in its work then such firms will find it good business policy to market only scientific preparations under truthful claims. Then the Council will be able to give such products the recognition they deserve—a recognition which the profession should demand as a prerequisite to their use.

Today the situation is decidedly better. All of the more important pharmaceutical houses cooperate with the Council to a very considerable degree. This in turn means that the thoughtful physician who buys or prescribes his drugs with scrutinizing care is supporting those concerns which market scientific preparations under truthful claims. This does not mean to be sure that some of these producers do not engage in practices that the Council does not approve, but it does mean that these houses are taking heed increasingly of the favorable attitude of the profession toward the Council.

There are many products which do not stand accepted by the Council for well defined reasons. Some members of the profession unfortunately, use products that are a distinct detriment to progressive medicine—a practice which encourages the producers to follow policies directly opposed to those of the American Medical Association and thus hinders the efforts of the Council and the Association to advance the cause of scientific medicine. As more and more of these men awaken to their responsibility the cause of rational therapeutics advances. The Council stands in the forefront of this advance.

#### PUBLICATIONS OF THE COUNCIL

*New and Nonofficial Remedies*—New and Nonofficial Remedies is in a constant state of revision. Supplements are issued throughout the year in order to keep subscribers informed of the products found acceptable in the interim between editions.

The U S Pharmacopeia XI and the National Formulary VI were issued in the latter part of 1935, though they will not become official until June 1 1936. It has required a considerable amount of time of the Council and its staff to revise New and Nonofficial Remedies to agree with descriptions of products in the new U S Pharmacopeia and the new National Formulary. Of the new additions to the Pharmacopeia many are products which stood accepted by the Council for New and Nonofficial Remedies and for which the A M A Chemical Laboratory had elaborated standards.

As is usual the 1936 volume of New and Nonofficial Remedies will contain additions of new drugs and notice of the omission of others. Considerable study has been given to the entire problem of vitamins, with the result that that section dealing with these products has been radically edited. The same applies to serums and vaccines and to other chapters.

During 1935 a number of new drugs were accepted by the Council. Among these were the following: Aminoacetic Acid (Glycocoll, Glycine), proposed for ameliorative treatment of such conditions as myasthenia gravis and progressive or pseudohypertrophic muscular dystrophy; Larocaine Hydrochloride, another local anesthetic of the procaine type; Alurate, Sodium Alurate and Ipral Sodium, additional barbitol compounds; Ephedrine Anhydrous and Ephedrine Hemihydrate, which replace the formerly accepted ephedrine alkaloid, Azochloramid, a new chloramine preparation claimed to have some advantages over chloramine, dichloramine and solution of chlorinated soda; Beta-Lactose, proposed for use in infant feeding and as a supplementary food for adults. It differs markedly in physical properties from the well known alpha-lactose (milk sugar); Pyrethrum Ointment, containing an extract of pyrethrum flowers proposed for use in the treatment of scabies; Meningococcus Antitoxin for use in specific meningococcal infection; Staphylococcus Toxoid, containing the hemolytic and dermonecrotic toxins of *Staphylococcus pyogenes-aureus* and *albus* altered by the formaldehyde-detoxifying process of Burnet (modified from Ramon); Mapharsen, the hemialcoholate of 3 amino 4-hydroxy phenylarsine oxide hydrochloride proposed for use in the treatment of syphilis and Iodobismutol with Saligenin, a solution of sodium iodobismuthite and sodium iodide in propylene glycol containing saligenin and a small amount of acetic acid to replace the formerly accepted Iodobismutol.

#### *Epitome of the U S Pharmacopeia and National Formulary*

—A drastic revision has been made of this useful book, which has a wide circulation. It constitutes a valuable guide to those who wish to know what is and what is not official in the two new official compendiums, and it gives as well an epitomized opinion of the relative value of the respective drugs.

*Useful Drugs*—This is a selected list of drugs prepared under the direction and supervision of the Council on Pharmacy and Chemistry. This, too, has been thoroughly revised and brought into conformity with the new Pharmacopeia and with the best current information as to the uses and value of the drugs described.

*Hospital Practice for Interns*—The revision of the Council's publications will be concluded with the reconstruction of this handbook for interns published jointly by the Council on Medical Education and Hospitals and the Council on Pharmacy and Chemistry. It is anticipated that it will be a most valuable reference book not only for the intern but for the practicing physician as well.

#### REPORTS OF THE COUNCIL

The Council has continued to inform the medical profession as to preparations considered and found wanting. Among the products so discussed were Dinitrophenol, Ho-Mo-Sol, Imbak Preparations, Ply #1, Ply #2 and Ply #3, Rossum, Scott's Cod Liver Oil Concentrate Tablets, Shadocol and Vegemucene. It should be realized that these represent only a small portion of the adverse reports as increasingly producers decide to take off the market products which have been found to be not acceptable. Furthermore a number of the products were not of sufficient importance to warrant publication in *THE JOURNAL* and therefore these reports will appear in the Annual Reprint of the Reports of the Council on Pharmacy and Chemistry. There are many reports held in abeyance in order that the manufacturer may determine whether or not he can obtain

evidence to justify the claims. The Council permits such reports to be held in abeyance provided manufacturers agree not to promote the products actively during this period.

The Council by no means confines itself to publication of adverse reports. The descriptions of accepted products which appear almost weekly in THE JOURNAL are in themselves favorable reports. In addition the Council each year publishes noteworthy preliminary and special reports, many of which have been highly commended.

**Dinitrophenol**—When dinitrophenol was first brought to the attention of the profession, the Council issued a preliminary report. While recognizing the tremendous academic interest in this preparation, it warned the profession against the use of the drug on an extensive scale until adequate clinical evidence was available to show its harmlessness. During the time of its introduction and through 1935 the Council and also THE JOURNAL issued reports of warning. The Council refused to accept for inclusion in New and Nonofficial Remedies brands submitted to it. The conservative stand of the Council proved valuable in the light of the experience with this drug which shows it to be potent for irreparable harm in certain instances.

**Standardization and Labeling of Liver and Stomach Preparations for Use in the Treatment of Pernicious Anemia**—A report designed to create a greater degree of uniformity and accuracy in the potency declarations of the marketed liver and stomach preparations was prepared by the Council. This entailed much work and extensive consultation with authorities in the field. Since the publication of this statement (THE JOURNAL, Oct. 19, 1935, p. 1269) manufacturers have been in a position to assay their products according to a relatively uniform acceptable method. This permits a more accurate therapeutic evaluation of these products and gives the practicing physician a basis on which to determine within an approximately accurate range the potency of the preparations he is importuned to use. The statement of the Council has been received with unusual interest not only in this country but abroad.

**Thromboplastic Substances**—A hospital informed the Council that it had found a certain brand of Thromboplastin apparently to be the cause of some unusual sequelae in cases in which it was used as a topical hemostatic agent. Specimens of the product were purchased on the open market and a bacteriologic examination was made. Specimens of one of the brands were found to contain dangerous pathologic organisms. As a result the manufacturer withdrew the product from the market and all manufacturers of accepted thromboplastic preparations have sent protocols indicating the methods whereby the sterility of their products is controlled.

**Shotgun Vitamin Therapy**—Thirty years ago was the heyday of shotgun therapy in drugs. The theory was that, if careful diagnosis could not be made, the patient should be given a blunderbuss charge of drugs with the hope that one of them would hit the spot. A recurrence of this type of careless thinking today is occurring in the vitamin field where there is a tendency to give all sorts of combinations with vitamins and minerals when in reality it is but seldom that multiple avitaminosis occurs. Furthermore, there appears to be no more reason for combining the vitamins than there is for combining any of the other thirty-seven essential dietary constituents. In an article entitled 'Shotgun Vitamin Therapy' the Council pointed out that mixed vitamin therapy is on insecure ground and it will not accept mixtures of vitamin concentrates until the manufacturers are able to present adequate evidence of their rationality. The burden of proof for claims always lies on the one making the claims.

**Ethical 'Patent Medicines'**—A classic procedure of manufacturers of pharmaceuticals has been first to make an effort to introduce a product to the profession and if it was not taken up by the profession then to permit it to go to the public. During the year the Council issued a report on 'Vegemucine Not Acceptable for N. N. R.' This report provides an example of what may happen when a new firm with only a few established products introduces a preparation of mediocre value to the profession and fails to obtain Council acceptance. In the present case the firm is now marketing its ulcer treatment directly to the laity in true 'patent medicine' style.

**Vitamin A in Urinary Lithiasis**—The occurrence of urinary calculi in rats may be associated with a deficiency of vitamins in the diet. This fact has been pointed out by certain clinicians and also by some watchful proprietary houses in order to suggest to the profession the use of vitamin A in the case of urinary lithiasis in human beings. A comprehensive report, requiring much time and effort on the part of the consultant who was asked to prepare it, was presented to the profession. This report showed a lack of evidence of the value of vitamin A in such conditions. In the light of this report it seems unlikely that manufacturers will be so bold as to advance blatant claims for the use of vitamin A preparations in the prevention and treatment of urinary lithiasis. The sad commentary, however, is that such claims were made before a critical survey had been published.

#### SPECIAL INVESTIGATIONS

**Catgut Sutures**—During 1935 the Council authorized an investigation of the market supply of sutures. Work has been started under the auspices of a special committee of the Council. It is anticipated that it will be a year before this work is sufficiently advanced to warrant the Council's issuing its report. While sutures do not come directly in the purview of the Council on Pharmacy and Chemistry, it was felt that the examination could be made better under the Council's supervision, because of its facilities for such investigations.

**Glandular Physiology and Therapy**—For the past few years the field of organotherapy has grown so rapidly that the Council thought it advisable that there should be an outstanding series of articles on both the physiology and the therapy of these products. Thirty-two articles were published in successive issues of THE JOURNAL in 1935. The Council's ability to obtain the services of the experts who contributed these articles, not only in the United States but in foreign countries as well, shows how highly the work of the Council is regarded. The vast amount of time and effort expended in this comprehensive review is illustrated when one considers the size and the scholarly paraphernalia of the bound volume of these articles. Incidentally, the articles were revised after publication in THE JOURNAL and previous to issuance in book form. As an indication of the high regard in which this book has been held there have been requests from nine countries asking for the privilege of translation. As a result of this series of articles the Council will be in a better position to evaluate the status of proprietary glandular products.

The matter of nomenclature for glandular products is in a chaotic condition. The Council therefore has appointed an Advisory Committee on the Nomenclature of Endocrine Principles which consists of sixteen experts most of whom contributed to the series of articles just discussed. This group is now endeavoring to bring about some degree of uniformity in endocrinologic terminology. It is anticipated that the reports of this committee will be made available to the profession in the next few months. Thus, not only will the physician be aided in having a language by which he may determine similarity or dissimilarity of the various glandular products he is importuned to use but medical literature as well will be benefited by the uniform terminology.

**Nonspecific Protein Therapy**—There were also published under the auspices of the Council two articles on nonspecific protein therapy written by Dr. Ludvig Hektoen and Dr. Russell L. Cecil. These contributions should aid in overcoming the chaotic state of present knowledge of this subject. They are particularly valuable in view of the questionable proprietary products of this kind which are currently "detailed" to physicians.

#### PROBLEMS BEFORE THE COUNCIL

In the report to the Trustees last year the Council discussed the use of letters and numbers in names reporting its gratification that in the case of all accepted products having numbers or letters in connection with names the manufacturers, with one exception agreed to omit them from the name. The single exception was Hexylresorcinol Solution S. T. 37. The Council is now gratified to report that the firm has indicated that it has ceased advertising the product to the public in the manner in which it was being done and has decided not to use the number in connection with the name. Pharmaceutical manu-

facturers themselves are apparently pleased by the Council's ruling on numbers, which ameliorated a condition that had already become chaotic.

**Committee on Vitamins**—The confused vitamin situation caused the Council to suggest to the Committee on Foods the formation of a Cooperative Committee on Vitamins representing the two groups. The members of this committee, composed of Prof W E Anderson, Dr E M Bailey, Dr K D Blackfan, Dr S W Clausen, Dr Morris Fishbein, Dr P C Jeans, Dr E M Nelson, Dr W W Palmer, Dr G F Powers, Dr L J Roberts, Dr M S Rose and Dr Torald Sollmann, were in session for a day and a half considering reports of referees on special vitamin problems. Knowledge in the field of vitamins has grown so rapidly and the methods under which vitamin products are prepared and marketed have changed so greatly that it was necessary for the Council to formulate certain guiding principles for the benefit of both manufacturers and the profession. These concern the revision of the dosage of cod liver oil in view of its increased potency, the problem of the use of antioxidants, permissible claims for vitamins A, B, C and D, minimum daily dosage of vitamins B and C that would be significant, the irrationality of certain vitamin combinations, the lack of evidence for vitamin E requirements in the human being, the matter of vitamin D fortification of milk as well as the general problem of fortification of foods, together with a number of collateral questions. Both the Council and the Committee on Foods have acted on these considerations and are preparing statements for publication.

The Council regrets that one state medical society, whose journal supports the Council in its advertising pages, has seen fit to criticize the Council without first making inquiry to determine the facts. In this particular instance the charges were based on the most flimsy evidence and are untrue. Had the medical society taken the pains to inquire, it would seem certain that it would not have made the charges that it did. As it is, a pharmaceutical concern whose products are not accepted has taken up charges of the state medical society and broadcast them in its house organ. In the interest of fairness, if for no other reason, it would seem reasonable to expect that a constituent part of the American Medical Association would refrain from making such charges until inquiry has been made to ascertain the facts in any given case.

#### REORGANIZATION

At times certain problems of the Council on Pharmacy and Chemistry, the Committee on Foods, and the Council on Physical Therapy overlap as a result it became apparent that each group has been maintaining separate offices and personnel for individualized work of interest to all three groups. It therefore seemed advisable that the work of these departments should be better correlated and that the offices be brought under one executive management. To do so required changes in physical arrangements, which was one of the contributing causes to the necessity of an enlarged building program. A plan, acceptable to all three groups, has been devised as follows: (1) that the administrative work of the three councils in the headquarters office be correlated under an executive secretary; (2) that a Committee on Policy, Rules and Procedure be established for the three groups, which will make recommendations on these matters. It is understood that the Committee on Policy, Rules and Procedure will suggest but not direct the work of the groups. The councils and the Committee will continue to function as single entities. The work of reorganization is now under way.

#### MEMBERSHIP OF THE COUNCIL

During the year the Council lost by death a most valuable member, Prof Lafayette B Mendel. Professor Mendel had served well the Association, both as a member of the Council since 1917 and as a member of the Committee on Foods since its inception in 1929. The Council issued a commemorative statement on the work of Professor Mendel which was published in *THE JOURNAL* Feb 15, 1936, page 539. During 1935 Dr Stanhope Bayne-Jones, Dr Kenneth Blackfan and Dr Eugene Du Bois resigned from the Council because of increasing responsibilities which they were forced to assume in connection with their academic work. These gentlemen have continued to aid the Council. Dr George H Simmons who has

been a member of the Council since its inception in 1905 and under whose direction the Council was founded, felt compelled to give up active participation in its work. In view of his long and valuable services, the Board of Trustees, at the suggestion of the Council, was pleased to confer on him an honorary life membership in the Council. The following new members were elected to fill the vacancies created by the three resignations: Dr David P Barr, professor of medicine at Washington University, St Louis, Dr S W Clausen, professor of pediatrics University of Rochester, Rochester, N Y, and Dr E M Nelson, chief of the Vitamin Division, U S Department of Agriculture, Washington, D C.

#### Summary

*The Council has completed thirty years of service. Conditions today are decidedly better, though there are still some physicians who have not yet fully realized the detrimental influence of certain types of low grade pharmaceutical concerns. However, the scientific standing of the average pharmaceutical house is vastly improved.*

*During 1935 a number of new and unusual drugs were accepted by the Council for inclusion in New and Non-official Remedies.*

*Useful Drugs and the Epitome of the U S Pharmacopeia and National Formulary have been thoroughly revised to bring them into conformity with the new Pharmacopeia and the new National Formulary. They enjoy wide distribution.*

*The Council has continued the issuance of reports on the status of untried or previously unannounced drugs. It is still looked to for the standardization of new products.*

*The Council has under way a special investigation of catgut sutures.*

*The series of articles on Glandular Physiology and Therapy reports on a much needed survey of this field and has been a decided aid in evaluating the status of proprietary and nonproprietary glandular products. The articles have been published in book form. Requests for the privilege of translating the articles have been received from nine different countries.*

*The Council published two articles on Nonspecific Protein Therapy, which should aid in overcoming the chaotic condition of this subject.*

*The Council on Pharmacy and Chemistry and the Committee on Foods have formed a Cooperative Committee on Vitamins. This committee has made recommendations on vitamin problems, the decisions on which are soon to be issued. It has been emphasized to physicians as well as to manufacturers that in this field particularly a conservative attitude, based on adequate clinical evidence, is the criterion of sound therapeutic progress.*

*The Council on Pharmacy and Chemistry, in cooperation with the Council on Physical Therapy and the Committee on Foods, has adopted a reorganization plan which provides for a federation of the administrative work of the three groups and a correlation of overlapping problems.*

*Physicians are making increased use of the conclusions of the Council on Pharmacy and Chemistry, as evidenced by the increase in work.*

#### Chemical Laboratory

Among the important alterations made in the building of the Association will be those concerned with the Chemical Laboratory. The facilities of the Laboratory will be greatly improved and extended through the provision of a room accurately air conditioned, which will permit micro analysis, and of a second room properly equipped for physical work of such nature as requires the greater use of optical instruments than has heretofore been permitted. The capacity of the Laboratory will be somewhat enlarged and with the improvements to be installed the accuracy as well as the scope of the Laboratory's work will be considerably enhanced.

The activities of the Chemical Laboratory have been carried out along previously established lines. A number of important

new products have been examined for the Council on Pharmacy and Chemistry, and the careful scrutiny that has heretofore been maintained with respect to certain widely used products has been continued in order to insure that these products shall be made available to the profession in potent form and in accurate dosages.

A very considerable amount of the Laboratory's work has been concerned with arsenicals and mercurials, bismuth compounds and the examination of dyes and other products of important chemical groups.

The Chemical Laboratory has continued to cooperate as fully as possible with other departments of the Association.

### Council on Physical Therapy

For ten years the Council on Physical Therapy has actively prosecuted its assigned work of analyzing, investigating and reporting on physical therapy methods. Through the columns of *THE JOURNAL*, reports on investigations of apparatus, surveys of physical therapy treatments, and special articles on specific problems have been made available to the profession. In the ten years of its active existence there has been a growing appreciation by the profession of physical therapy.

The interests and activities of the Council in 1935 have been focused on the instruction of the practicing physician concerning effective physical therapy methods, the improvement of curriculums for college physical therapy courses, the development of better modes of treatment, and the consideration of apparatus.

### EDUCATIONAL ACTIVITIES

Sixteen articles on physical therapy and related subjects have been prepared by specialists and, after adoption by the Council, published in *THE JOURNAL*. These authoritative articles have apparently been favorably received by the profession, since numerous requests for reprints of them have been made by inquiring physicians. The Handbook of Physical Therapy is undergoing a thorough revision, and a number of the aforementioned articles will be incorporated in the volume. In all its publications the Council endeavors to point out the importance of physical therapy as an adjunct in treatment, rather than as an all inclusive, independent agency.

The Council has cooperated with the Council on Medical Education and Hospitals in the formulation of standards for curriculums for schools of physical therapy technicians. A registry operated under the direction of the American Congress of Physical Therapy has been prepared, and the two councils have cooperated with the congress in this work. It appears that most class A medical schools have made some provision for physical therapy instruction. Hence the physician of tomorrow will have a working knowledge of this branch of therapy, but for the general practitioner of today who has been out of touch with some of the recent developments, the Council believes that a comprehensive program of extension instruction is needed.

Because a certain number of general practitioners obtain their information on physical therapy through contact men representing manufacturers of apparatus, the Council feels that a very narrow view of the possibilities of physical therapy is imparted to them. For this reason the Council is now in a position to suggest, through its group of consultants on education, qualified speakers on the simple methods of physical therapy which may be practiced by any physician without the use of expensive apparatus. In the opinion of the Council, at least 90 per cent of physical therapy treatments can be given by simple measures, such as heat, massage and exercise. Foregoing personal gain, Council members, consultants and specialists in physical therapy have accepted invitations from state and county medical societies and have donated their services freely, reading papers and giving demonstrations.

Motion pictures dealing with fundamental and practical aspects of physical therapy methods are available for loan. They may be borrowed by writing to the secretary of the Council.

In addition to the exhibit at the regular annual session at Atlantic City, the Council has sponsored exhibits on physical therapy in cooperation with the Bureau of Exhibits of the Association at ten state, county and special medical society meetings.

### CONSIDERATION OF APPARATUS

Probably one of the most important educational programs of the Council is the publication of reports on the consideration of submitted apparatus. Many machines are constantly being manufactured and sold to the physician and the public, involving the use of various physical agents, such as high frequency electrical energy, radiant energy and manipulative exercise. The Council investigates such appliances and accepts for its official lists those which are believed to have merit. Any which are believed to be worthless or harmful are made the subject of adverse reports. During the year the Council considered seventy-seven pieces of apparatus. Of this number forty-two were accepted, three were rejected, and the remainder are still under consideration. Other appliances have been submitted to the Council, but the requirements for submission have not been completed by the promoters. Therefore they have not been formally considered. In some instances, devices for which extravagant claims have been made, and which involve nothing new in principle, have been withdrawn from the market as the result of anticipation on the part of the manufacturer of the publication of a disparaging Council report.

A booklet entitled "Apparatus Accepted by the Council on Physical Therapy" has been prepared, in which accepted devices and their indications are given. This booklet has been rather widely distributed to physicians requesting information on accepted apparatus.

Because of the demand for reliable information, the Council has agreed to consider shoes and orthopedic appliances for which claims of a therapeutic nature are made. Therefore, standards for considering shoes have been formulated. Cooperation has been maintained with the Council on Pharmacy and Chemistry and the Bureau of Investigation of the American Medical Association, the Better Business Bureaus of various cities, the National Bureau of Standards, and the American Standards Association. This cooperation has aided the Council in furnishing reliable information.

Consideration of ophthalmologic devices, including lenses and retinoscopes, has been carried on. Some useless devices have been kept off the market through the cooperative efforts of the Committee on Standardization of Instruments and Drugs of the Section on Ophthalmology of the American Medical Association with the Council on Physical Therapy.

In the course of the year the Council has considered positive and negative pressure apparatus, oxygen tents, resuscitating apparatus, infra-red and ultraviolet generators, orthopedic appliances, radium and radon products, and x-ray equipment. Hearing aids and audiometers have been considered by the Council, assisted by the American Society for the Hard of Hearing. The Council is greatly indebted to a number of physicians in various parts of the country, who have rendered most able assistance in promoting its work. Because of the large number of devices that have been considered, the volume of correspondence has greatly increased.

### SHORT WAVE DIATHERMY

A large share of the Council's time has been devoted to the consideration of short wave diathermy equipment. In view of the misleading and unwarranted statements formerly made for these devices, the Council was obliged to make a special study of them and report its conclusions. After due investigation the Council went on record to the effect that the therapeutic efficacy of short wave diathermy was attributed only to the heat generated in the tissues of the body and not to any specific biologic or bactericidal effect. Fourteen short wave diathermy machines have been accepted, although at the present time there appear to be some thirty or more manufactured and offered for sale to the profession.

During the past year progress has been made in research. Six grants were awarded. Eleven articles were published during 1935 on specialized fields of physical therapy, as a result of grants awarded the year before. Applications for grants in aid of research may be obtained from the secretary. These grants are awarded for purchasing material and instruments and not for compensation or salaries.

### Summary

During the year 1935 the work of the Council on Physical Therapy has been focused on (1) extension instruction for the general practitioner, (2) consideration of apparatus and publication of reports, (3) investigation of new physical therapy methods having a semblance of practicability

**Educational Activities**—Sixteen articles on physical therapy and related subjects prepared by Council members and by other specialists have been adopted and published in *The Journal*. Most of these articles are included in the thoroughly revised *Handbook of Physical Therapy*.

This council has cooperated with the Council on Medical Education and Hospitals in formulating curriculums for schools of training for physical therapy technicians and has cooperated with the American Congress of Physical Therapy in establishing a registry for technicians. This important work is designed to maintain high standards in the practice of physical therapy.

Aided by its consultants on education the Council has suggested to many county and state medical societies qualified speakers on physical therapy subjects. These speakers have stressed the importance of using simple physical therapy methods readily available to the practicing physician in contrast to the therapeutic value of expensive apparatus. Exhibits on physical therapy subjects have been sponsored at ten county state and special medical society meetings.

**Investigation of Apparatus**—Seventy-seven pieces of apparatus have been considered of which forty two were accepted and three were rejected. The remaining thirty-two are still under consideration. Reports have been published on special investigations sponsored by the Council. A booklet entitled "Apparatus Accepted by the Council on Physical Therapy" has been prepared and has been widely distributed to physicians requesting information on accepted products.

Standards have been formulated and adopted for the consideration of shoes and orthopedic appliances. Cooperating with the Committee on Standardization of Instruments and Drugs of the Section on Ophthalmology of the American Medical Association the Council has investigated lenses, retinoscopes and other ophthalmologic devices.

Apparatus the Council has considered falls into the following groups: infra-red and ultraviolet generators, orthopedic appliances, surgical supports, positive and negative pressure apparatus, oxygen tents, resuscitation apparatus, radium and radon products, x-ray equipment, hearing aids, audiometers, and surgical and medical diathermy apparatus. Of the thirty or more short wave diathermy machines manufactured and offered for sale to the profession, only fourteen have been accepted.

Six research grants were awarded. Eleven articles dealing with physical therapy problems were published in various journals as a result of grants awarded previous to 1935.

### Bureau of Legal Medicine and Legislation

#### FEDERAL LEGISLATION

A summary of federal legislation of interest to physicians was published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* 31:18 (Jan.) 1936. The measures of outstanding importance are the Social Security Act and the Copeland food drugs, devices and cosmetics bill.

**Social Security Act**—This act imposes certain federal taxes on employers and employees. It proposes through the use of a part of the proceeds of such taxation to penalize the inhabitants of such states as do not levy taxes of a similar character for some of the purposes of the act. The proceeds of such federal and state taxation, supplemented by a considerable addition from money derived from general federal and state taxes are to be used for old age "assistance," old age benefits, unemployment compensation, vocational rehabilitation, child welfare services and to dependent children, assistance to crippled children,

maternal and child health activities, aid to the blind, state public health administrative activities, and research in the field of public health and sanitation.

The taxes imposed by the Social Security Act have no specific relation to practitioners of medicine. Such practitioners are liable for such taxes only as they are employers and employees, and the taxes imposed on them as employers and employees do not differ in any way from the taxes imposed on all other employers and employees. The provisions of the act so far as they relate to the taxation of physicians and hospitals were discussed in *THE JOURNAL*, Jan. 25, 1936, page 322. An analysis of the act in its entirety was published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* 31:42 (Feb.) 1936. The taxation and subsidy features of the Social Security Act are based on the hypothesis that the federal government has the right through taxation and state subsidies, to induce or compel states to enact legislation that is in essence dictated by the federal government for purposes predetermined by the federal government. The soundness of this hypothesis has been questioned, but pending a determination by the United States Supreme Court the medical profession should cooperate in good faith in carrying out the provisions of the act.

**Federal Health Insurance**—Specific reference to health insurance was deleted from the Social Security Act before it passed. The act however authorizes the Social Security Board to investigate "social insurance" and social insurance covers health insurance. It is quite within the range of possibility, therefore, that the board may in due time undertake the investigation of health insurance. At present (March 17) there is no evidence of its intention to do so.

In the Senate a resolution is pending before the Senate Committee on Education and Labor, proposing to authorize that committee to make a complete investigation to determine the best and most effective kind of legislation to provide a system of health insurance. In the House of Representatives a bill proposing a general system of social insurance including health insurance for workers and farmers was favorably reported by the Committee on Labor before the enactment of the Social Security Act for which act it was unsuccessfully offered as a substitute in the course of the debate. It is hardly too much to say that there is no likelihood of any federal health insurance legislation during the current year.

**Food, Drugs, Devices and Cosmetics Legislation**—Seven bills were before the Seventy-fourth Congress relating to food, drugs, devices and cosmetics. The Senate Committee on Commerce through a subcommittee held hearings on the several pending Senate bills and subsequently reported to the Senate with amendments. S. 5 commonly referred to as the Copeland bill. The Bureau of Legal Medicine and Legislation cooperated to the extent of its ability with the Senate committee and with the Food and Drug Administration of the Department of Agriculture in efforts to bring about the enactment of an effective law. The bill reported however in the form in which it was passed by the Senate gives in its entirety hardly more promise of effectiveness than does the law now in force the Food and Drugs Act of 1906. So far as it relates to drugs, it is distinctly weaker. The Bureau has made efforts to have the bill amended or rewritten by the House Committee on Interstate and Foreign Commerce before which it is now pending so as to make it effective legislation if it is enacted.

**Medical and Hospital Care for Employees on Emergency Relief Rolls**—The Emergency Relief Appropriation Act of 1935 approved April 8, 1935 materially modified the medical and hospital benefit provided for employees on emergency relief payrolls. Under an administrative ruling made under the act unemployed persons were classified as employable and "unemployable." Unemployable persons were such as were physically or mentally incapacitated and unfit for employment even if employment should be offered them. Employable persons were persons not so handicapped. Under the new order, all employable persons were turned back on the several states and their political subdivisions for relief, the federal government assuming no responsibility for their medical or hospital care. For employable persons on relief, the federal government set up an organization which it denominated the Works Progress Admin-

istration, commonly referred to as the WPA. Under the Civil Works Administration, which preceded the Works Progress Administration, all employees had been entitled to the medical and hospital benefits afforded regular employees of the federal government. Under the Works Progress Administration, however, employees are entitled to such benefits only when they are suffering from traumatic injury incurred in the line of duty, for disease contracted in the line of duty, unless it can be traced directly to trauma, the employee is entitled neither to medical nor to hospital benefits. Such medical and hospital care as is provided is given through the United States Employees' Compensation Commission, in accordance with the terms of the United States Employees' Compensation Act of 1916, as amended.

The fact that employees in the Works Progress Administration are entitled to medical and hospital benefits only in event of traumatic injury incurred in the line of duty, and the fact that the compensation paid such employees is ordinarily inadequate to enable them to provide adequately for the care of their dependents, have tended to throw back on the states and their political subdivisions the problem of providing hospital and medical care in such cases, notwithstanding the fact that the head of the household is an employee of the United States government and in receipt of government wages.

Incidentally, a similar situation seems to have arisen in connection with the activities of the Rural Resettlement Administration, whose wards in rural resettlement projects seem to have been, in some cases at least, so poorly provided for in the way of money and other benefits as to render it difficult for them to provide adequate medical and hospital service for themselves and their families and to throw on the local community and particularly the local medical profession the problem of caring for them in event of illness, injury and childbirth.

In the discharge of its duties under the Works Progress Administration, the United States Employees' Compensation Commission has cooperated with the Bureau of Legal Medicine and Legislation and with the several national hospital associations in efforts to devise plans whereby to provide adequate medical and hospital care for injured workmen and yet to provide reasonable compensation for the physicians and hospitals rendering service. That the plans worked out have operated satisfactorily, on the whole, is shown by the absence of complaints from individual physicians and from organizations. The only complaint of moment that has been received related to the furnishing of roentgenograms by hospitals a matter that in some of its aspects has been before the House of Delegates on previous occasions but which apparently has not been settled to the satisfaction of all interested parties.

*Veterans' Legislation*—During the first session of the Seventy-Fourth Congress forty-six bills were introduced proposing to erect either new hospitals or domiciliary facilities for veterans or to enlarge existing facilities. Presumably as a result of the public hearings on these bills, the Second Deficiency Appropriation Bill carried an appropriation of \$21,250,000 for hospital and domiciliary facilities. It is not contemplated that any new hospitals will be erected out of this appropriation. According to the report of the House Committee on Appropriations the appropriation is to provide a total of 11,466 beds at thirty-eight existing veterans' hospitals and domiciliary institutions: 6,835 beds for neuropsychiatric patients; 455 beds for tuberculous patients; 2,276 general medical beds and 2,250 domiciliary beds. This represents a building program for a five-year period, according to the Administrator of Veterans Affairs. Yet already Congress is being importuned to appropriate still other sums for hospitals for veterans. One bill proposes to erect a 300-bed hospital in western Texas; apparently a general hospital, another to provide for the enlargement of the veterans hospital at San Fernando, Calif. to accommodate tuberculous patients, a third to construct a new wing of approximately 350-bed capacity on the veterans general hospital at Los Angeles.

No legislation has been introduced in Congress since the last report to the House of Delegates proposing to enlarge the privileges of veterans with respect to medical care and hospitalization.

*Reserve Officers Training Corps*—Pursuant to action taken by the House of Delegates action was initiated looking toward

the continuation of medical units in the Reserve Officers' Training Corps. The War Department Appropriation Bill, as it passed the House of Representatives Feb. 14, 1936, however, contained the proviso that has been incorporated in all such bills since 1932 prohibiting the expenditure of money from the appropriation for the Reserve Officers' Training Corps, for the maintenance of medical units. As passed by the Senate, that prohibition was eliminated. It seems not improbable, therefore, at the present writing, that the training of medical students for military service in case of need will be resumed at an early date. It is hoped that the medical colleges of the country will cooperate in making such training effective.

*Reorganization of Federal Narcotic Service*—For the purpose of increasing the efficiency of the several police services of the Treasury Department, a bill was introduced in the House of Representatives Feb. 25, 1936, proposing to create in that department a Secret Service Division, to be made up of the enforcement division of the Alcohol Tax Unit of the Bureau of Internal Revenue, the Customs Agency Service of the Bureau of Customs, and the Bureau of Narcotics. Under this proposed reorganization, the Commissioner of Narcotics would no longer be responsible directly to an assistant secretary of the treasury but would report to the chief of the Secret Service Division. He would continue to perform, however, all functions performed under treaties to which the United States is a party, so far as such functions require communication or cooperation with foreign governments, all functions relating to cooperation with the states (including the development of state laws), all functions relating to the development of treaties with regard to the supervision and control of traffic in narcotic drugs, and the function of supervising the legitimate traffic in narcotic drugs. In view of strong representations made on behalf of the Treasury Department that the proposed plan of reorganization would contribute materially to efficiency, no sufficient reason appears for opposing the enactment of this bill. The objection raised on behalf of pharmacists and others interested commercially in narcotic drugs, that it would bring legitimate professional and business men under the surveillance of officers and agents of the Secret Service Division, seems hardly sufficient to justify opposition to the plan proposed as a method for increasing the efficiency of the enforcement of certain federal laws, among them the laws relating to narcotic drugs.

*Contract Surgeons of the Spanish-American War*—Pursuant to the action of the House of Delegates, the Bureau of Legal Medicine and Legislation has endeavored to obtain for contract surgeons of the Spanish-American War benefits similar to those accorded to other participants in that conflict, more particularly such as have already been accorded to contract nurses. Unfortunately, the beneficiaries of such proposed legislation are not organized and vocal, and the efforts of the Bureau have struck no responsive chord in Congress.

*Investigation of Silicosis and Other Occupational Diseases*—Predicated on a considerable number of cases of silicosis alleged to have resulted from the digging of a tunnel at Gauley Bridge, W. Va. a resolution was introduced in the House of Representatives Jan. 13, 1936, proposing to authorize the Secretary of Labor to appoint a board to investigate the health conditions of workers employed in the construction and maintenance of public utilities. The House Committee on Labor, to which the resolution was referred held hearings on the resolution. The Bureau of Legal Medicine and Legislation brought to the attention of the committee the work on silicosis already undertaken by the United States Public Health Service and by the Bureau of Mines and suggested that representatives of the bureaus named be called before the committee. Following the hearing, the chairman of the House Committee on Labor introduced another resolution proposing to authorize the Committee on Labor, or a subcommittee to make an investigation concerning the health conditions of workers employed in the construction and maintenance of mining and tunneling projects, with particular reference to silicosis and other respiratory diseases. This resolution is pending before the Committee on Rules of the House. A Senate concurrent resolution proposes that a joint committee, made up of Senators and Representatives, make a similar investigation with respect to the diseases of metal miners. No good reason appears why investigations of this type should not

be conducted either by the Public Health Service or by the Bureau of Mines, or cooperatively by both, instead of by congressional committees

**Birth Control Legislation**—Six bills are now pending in Congress to legalize the dissemination, under conditions stated in the bills, of information, preparations and devices designed, adapted or intended for the prevention of conception. Three bills are pending designed to facilitate the prosecution of persons who send such information, preparations, devices, and indecent and obscene articles through the mail

#### STATE LEGISLATION

A survey of state legislation of interest to the medical profession was published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* 30 121 (Nov.), 152 (Dec.) 1935. Throughout the year, when state legislatures were in session, reports of the activities of state legislatures so far as they might have a direct bearing on the medical profession were published in the news columns of *THE JOURNAL*, and the Bureau of Legal Medicine and Legislation was in constant correspondence with constituent state medical associations in those states to which such legislation related. The more important measures of interest to the medical profession are discussed herewith.

**Health Insurance**—Bills proposing the establishment of systems of compulsory state health insurance were considered in the legislatures of six states, namely, California, Illinois, Massachusetts, Nebraska, New York and Pennsylvania. None of the bills considered in those states were enacted. Most of them were patterned closely after the bill described by its proponents as a "Social Security Bill for Health Insurance" but which soon became popularly known as the "Epstein bill," because of the activities of one Abraham Epstein, the secretary of the American Association for Social Security, by which the bill was prepared, drafted and sponsored. California health insurance legislation attracted an unusual amount of attention because it was introduced after a lengthy investigation by a committee of the California senate and was supposed to have the support of the medical profession of the state. During the current year, 1936, at the present writing health insurance bills have been introduced in two of the nine state legislatures in regular session. These bills have been patterned after the Epstein bill.

**Professional Use of Narcotic Drugs**—The uniform narcotic drug act, drafted by the National Conference of Commissioners on Uniform State Laws, with the cooperation of the Bureau of Legal Medicine and Legislation, was enacted in 1935, with or without modification, in nineteen states, namely, Alabama, Arizona, Colorado, Connecticut, Delaware, Georgia, Illinois, Indiana, Maryland, Nebraska, New Mexico, North Carolina, Ohio, Oklahoma, Oregon, South Dakota, Utah, West Virginia and Wisconsin. So far in 1936 the uniform act has been enacted in one state, Mississippi. The act, in its original or in a somewhat modified form, is now in force in twenty-nine states. While there has been an effort to strengthen the act in some states by making it apply to cannabis and by providing for the commitment of addicts, both of which matters the National Conference of Commissioners on Uniform State Laws thought best to leave to the judgment of individual states, in too many cases the tendency has been covertly to weaken the act. The tendency has manifested itself particularly in modifications of the provisions of the model act designed to facilitate the sale of so-called exempt preparations, preparations that because of their relatively small narcotic drug content are allowed to be sold without prescription. Obviously, however, no matter how attenuated may be the narcotic potency of an exempt preparation, it will serve the purpose of a narcotic addict if he can obtain it in sufficient quantity and the modifications that have been adopted in some states are strongly suggestive of having been designed so as to permit the narcotic addict to do so.

There has been a distinct tendency to add cannabis to the list of so-called narcotic drugs covered by the uniform state narcotic drug act, and even in states in which that act has not come up for consideration, legislation has been proposed independently to regulate the production, preparation and distribution of cannabis. The drug according to common reports seems to be a public menace through its use under the designation of "marijuana," for the preparation of cigarettes.

Laws prohibiting the sale and distribution of certain hypnotic or somnifacient drugs, except on the prescriptions of licensed physicians, dentists or veterinarians, were passed in Alabama, Arkansas, Colorado, Maryland, Nebraska, Oregon and Pennsylvania. Legislation of this type is now in force in fourteen states.

Pennsylvania took cognizance of the danger incident to the indiscriminate distribution of cinchophen, atophan, atogumol and dimetophenol and prohibited the sale of such preparations except on physicians' prescriptions. In California a bill to restrict the distribution of dimetophenol and of thyroid extract passed the legislature but was killed by the governor through a pocket veto.

**Laws Relating to the Practice of the Healing Art**—A basic science act was enacted in Iowa. Medical practice acts were amended in Arizona, Arkansas, California, Connecticut, Georgia, Maine, North Carolina, Oklahoma, Oregon, Pennsylvania and Wisconsin. Laws regulating the practice of osteopathy were extensively amended in Iowa and in New Jersey, which will extend the scope of osteopathic practice. No chiropractic legislation was enacted except in Connecticut, where a law was passed permitting chiropractors to treat patients under the workmen's compensation act. No new naturopathic legislation was adopted.

A physicians' lien law was enacted in North Carolina permitting physicians to establish liens to secure payment when they treat persons injured through the fault of others, on such settlements and judgments as may accrue to the injured patient by reason of his injuries.

Gunshot and other wounds were made reportable by physicians treating persons so injured in Minnesota and New Hampshire. Reports are to be made to designated police officials.

**Hospital Service Corporations**—The formation of corporations to provide on a "nonprofit" basis for the hospital care of their members or subscribers was authorized in Alabama, California, Illinois and Maryland. The Alabama and California laws seem definitely to prohibit the rendering of medical and surgical services by such corporations under their insurance contracts, but the extent of the services that such corporations can render in Illinois and Maryland is not clear.

**Workmen's Compensation**—The workmen's compensation act in New York was amended so as to permit an injured employee to select his own physician from a roster of physicians prepared by the industrial commissioner on the recommendation of the medical societies of the several counties of the state. Physicians other than those recommended by such societies may be included on the roster on application to the commissioner. The commissioner is authorized to establish a schedule of fees for medical treatment and care. In New York, too, disability due to occupational disease of any kind in any employment covered by the workmen's compensation act was made compensable. In North Carolina twenty-five named occupational diseases were made compensable. In West Virginia, silicosis was made compensable.

**Miscellaneous Legislation**—Clinical laboratories must be licensed under a law recently enacted in California. In Oregon, a new law provides for the registration and regulation of laboratories in which human or animal body fluids, secretions or excretions are examined for the determination of the presence or absence of infectious agents.

Laws requiring a physical examination of applicants for marriage licenses were enacted in Connecticut and Montana. In New York and Wisconsin, laws were enacted permitting the introduction in evidence in certain cases, of the results of blood tests. Bills for the regulation of experiments on living animals were introduced in the legislatures of New York, Wisconsin and California but were not passed. Two bills introduced in Congress proposing to prohibit experiments and operations on living dogs in the District of Columbia are still pending.

#### UNITED STATES DEPARTMENT OF HEALTH

At the Special Session of the House of Delegates in Chicago in February, 1935 there was referred to the Bureau of Legal Medicine and Legislation and the Board of Trustees a resolution introduced by Dr. Charles E. Humiston, Illinois as follows:

WHEREAS The general welfare of the people of the United States depends to the highest degree on a favorable condition of the public health and

'WHEREAS, The health activities which are proper to the federal government are not now closely coordinated but are scattered among a number of unconnected administrative departments therefore be it

*Resolved* By the House of Delegates of the American Medical Association assembled in special session for the sole purpose of giving consideration to the present national emergency that we urge on the President and the Congress the advisability of bringing all governmental health matters together in a new department under a new cabinet member to be known as the Secretary of Health such new cabinet member to be a doctor of medicine —*Proceedings House of Delegates Special Session 1935 pp 5 and 9*

The President, Aug 15, 1935, created an interdepartmental committee to study the health activities of the federal government and closely related welfare activities, with a view to their better coordination. This committee is made up of an assistant secretary of the treasury, an assistant secretary of the interior, an assistant secretary of agriculture and a second assistant secretary of labor. It is authorized and directed "to assume responsibility for the appointment of special committees to be composed of physicians and other technically trained persons within the government service to study and make recommendations concerning specific aspects of the government's health activities." The President expressed the hope that through the appointment of this committee a "complete coordination of the government's activities in the health field" might be effected. Up to present writing the committee has not submitted its report.

More recently, Feb 26, 1936, under authority of a Senate resolution, the vice president appointed a special Senate committee to investigate all executive agencies of the government with a view to their coordination. This, of course, includes the agencies carrying on the public health activities of the government. The committee consists of Senator Byrd of Virginia, Senator Robinson of Arkansas, Senator O'Mahoney of Wyoming, Senator McNary of Oregon and Senator Townsend of Delaware. No report has been made by this committee up to present writing.

In this connection it seems proper to call attention to the extent to which the United States Public Health Service is now authorized to cooperate with the various other branches of the executive department and the independent offices of the federal government and with state agencies in the solution of their medical problems. This limits, of course the tendency toward the development of independent medical services in other branches of the government.

The law now provides that, on the request of the head of an executive department or an independent establishment which is carrying on a public health activity, the Secretary of the Treasury may detail officers and employees of the Public Health Service to such department or independent establishment to cooperate in such work. It provides specifically for the detailing of medical officers of the Public Health Service for cooperation in health, safety and sanitation work in the Bureau of Mines and for cooperation with the Department of Agriculture in the administration of the Food and Drugs Act of 1906 as amended. The Secretary of the Treasury is authorized and directed furthermore, to utilize the personnel of the Public Health Service, so far as may be possible in aiding to combat and suppress "Spanish influenza" and other communicable diseases in conjunction with the personnel and the facilities of the medical departments of the army and the navy, acting under the authority of the Secretary of War and the Secretary of the Navy, respectively.

The Surgeon General of the Public Health Service is authorized to cooperate with state and territorial boards of health, quarantine authorities and health officers of the several states and of the District of Columbia, and he may be required on the application of not less than five of such authorities to call a conference in the interest of public health. The law authorizes the Surgeon General to extend the facilities of the Public Health Service to health officials and scientists engaged in special study.

Affiliated with the Public Health Service is the National Institute of Health, which is the successor of the Hygienic Laboratory of the service. The institute has an advisory council the National Advisory Health Council to advise the Surgeon General with respect to public health activities and to

consult with him concerning the investigations to be undertaken by the service and the methods of conducting them. This council consists of three experts detailed from the army, the navy and the Bureau of Animal Industry, by the Surgeon General of the army, the Surgeon General of the navy and the Secretary of Agriculture, respectively, the director of the National Institute of Health, ex officio, and five members, not in the regular employment of the government, appointed by the Surgeon General of the Public Health Service, with the approval of the Secretary of the Treasury, skilled in laboratory work in its relation to public health.

Under the provisions of law as set forth, medical officers of the United States Public Health Service are now functioning in various civil branches of the federal government, the only independent public health service of any considerable magnitude being that of the Children's Bureau in the Department of Labor. An enlargement of the independent public health activities in the Department of Labor was threatened in a resolution introduced in the House of Representatives authorizing the Secretary of Labor to appoint a committee to investigate the prevalence of silicosis and certain other diseases incident to industry. This resolution, however, gave way to another authorizing such an investigation but providing that it should be made by the Committee on Labor of the House of Representatives. At the present writing this resolution has not been adopted. A similar resolution is pending in the Senate, looking toward the making of a similar investigation by a joint committee of the Senate and the House of Representatives, which likewise is awaiting action. A congressional investigation by a committee organized as is proposed by either of the resolutions referred to would doubtless avail itself of the resources of the Public Health Service in carrying on its work.

In view of the facts set forth and of the generally disturbed state of the machinery of the executive branch of the federal government on account of its ventures during recent years into new fields and its enlargement of old fields, the time seems hardly opportune to press for legislation looking toward the establishment of a department of health, and to propose that the President be limited to a single profession in his choice of a secretary of health would be without precedent in the appointment of a member of the cabinet. It seems now better to conserve and to promote the federal medical organization that exists and to bring into it as opportunity offers the important medical work of the Children's Bureau in the Department of Labor, rather than to undertake to procure the establishment of a department of health.

#### INTEGRATION OF THE MEDICAL PROFESSION

At the session of the House of Delegates at Atlantic City in June 1935 there was referred to the Board of Trustees for study, report and recommendation the matter of the so-called integration of the medical profession. The Board has to report that there have been no developments during the past year along the line of the integration of the profession. The House of Delegates is reminded that by the term "integration of the medical profession" is meant the organization by statute of all licensed practitioners of medicine within a state into a public corporation, authorized by law to determine who is and who is not eligible for admission into the profession and to supervise the conduct of every practitioner after he has been admitted, reprimanding practitioners and suspending and revoking their licenses as circumstances dictate. All functions of the medical examining and licensing boards of the states at the time of integration would be taken over by the integrated agency.

No adequate plan has been proposed whereby all persons engaged in the practice of the healing art, nonsectarian and cult practitioners alike might be brought into a single effective integrated agency and compelled to adhere to proper standards. Your Board of Trustees is not satisfied that the integration of the medical profession alone, without the integration of all cult practitioners into the same body would effect any good purpose or any advantage to the medical profession or to the public, and the Board knows of no way in which cult practitioners could be incorporated in any effective regulatory body on any terms that they would be likely to accept. To propose a plan of integration that would provide for the regulation of cult practice along rational lines would only arouse antagonism and bring into

activity their combined political resources and probably prevent the adoption of the plan. The Board does not believe that it would be advisable in the present state of affairs to advise state associations to undertake such contests. In some states they may be advisable. Your Board of Trustees recommends, therefore, that the matter of integration be kept in abeyance, for further study and for action if circumstances arise, except as in particular states local conditions may indicate a different course.

#### FREE CHOICE OF PHYSICIAN

The House of Delegates, at its special session in Chicago in February 1935, referred to the Bureau of Legal Medicine and Legislation a resolution offered by Dr. John W. Ames, Colorado, instructing the "appropriate officers and the legislative committee" of the Association to bring to the attention of the President of the United States and his advisers a request that proper steps be taken to provide for employees on federal projects free choice of physician. This matter must be considered in the light of the status of such projects that is according as they are being carried on directly by the federal government through its own employees or are being carried on through contracts.

If a federal project is being executed by employees of the federal government, then, under the United States Employees' Compensation Act of 1916, as amended in event of disability incurred in the line of duty, the injured employee if he is entitled to medical and hospital services, must be treated by a medical officer of the United States government and in a United States government hospital, if treatment can be so provided. Only in the event that it cannot be so provided may an injured employee be treated by other physicians and in other hospitals, and then only by physicians and hospitals approved or recognized by the United States Employees' Compensation Commission.

If public works are being carried on by the federal government under contracts and through contractors, the matter of providing medical and hospital care for injured employees devolves on the contractor not on the federal government. Under such circumstances it is regulated by the workmen's compensation act of the state in which the contractor's activities are carried on and the question whether the disabled employee has or has not the right to choose his own physician depends on the law of that state.

Strangely enough labor, which has been insisting on its rights with respect to so many things, seems to have been willing and to be willing to submit to the deprivation of what might almost be called a natural right, namely, the right to determine who shall and who shall not treat a workman when he is injured in the course of his employment. In view of that fact in view also of the state of flux in which the activities of the federal government have been carried on during recent years and are now being carried on and in view of the nature and extent of the sentiment and pressure for the enactment of medical legislation inimical to the best interests of the people, as well as of the medical profession, such as health insurance legislation it seems to be inopportune now to enter on a contest for the establishment of the right of the disabled employee of the federal government to choose his own physician.

#### COOPERATION WITH STATE AND COUNTY ASSOCIATIONS

The Bureau of Legal Medicine and Legislation has received the active support and cooperation of the several state and county medical societies affiliated with the American Medical Association and of many individual members of the organization. It has endeavored to render efficient service to all of them so far as its resources would permit. The result—flattering if at times inconvenient—has been constantly increasing demands on the Bureau. It must be recognized however that the Bureau cannot undertake to furnish legal advice to individual members of the Association concerning their personal legal problems. If it did so the Association might readily be charged with being a corporation engaged in the practice of law and the staff of the Bureau of Legal Medicine and Legislation would be open to the charge of aiding and abetting in the unlawful practice of law and of unethical practice. It would be far better for every state and every county association to employ its own legal adviser referring to the Bureau of Legal Medicine and Legisla-

tion, preferably through counsel, the problems in which the Bureau may be of service. State and county associations, too might well undertake to answer directly many of the questions that are propounded by their members to the Bureau of Legal Medicine and Legislation, for by doing so they would better impress on their members the value of the service rendered by the state and county association. Possibly it would be well for the Bureau of Legal Medicine and Legislation to conduct its correspondence with persons residing in any given state only through the office of the state medical association. In that way it would be relieved of much of its detail work and have more time for the study of the larger problems of the profession.

#### Summary

**1 Social Security Act**—*The Social Security Act is now law. Until it has been declared unconstitutional by the courts or repealed by Congress, physicians should cooperate in good faith to carry it into effect. The act does not refer to health insurance. It does authorize the Social Security Board to investigate and report concerning social insurance, and under this authority the board can investigate and report on health insurance. There is, however, no evidence of any immediate intention to do so.*

**2 Federal Food and Drugs Legislation**—*Legislation relating to food, drugs, devices and cosmetics has developed to a stage at which one bill, the so-called Copeland bill, S 5, has passed the Senate and is pending in the House of Representatives, before its Committee on Interstate and Foreign Commerce. On the whole the bill passed by the Senate gives no promise of protection to the people more effective than that afforded by the Food and Drugs Act of 1906, which this bill is intended to supplant. The provisions of the pending bill with reference to drugs are distinctly weaker than are those now in force. An effort is being made to bring about a revision or rewriting of this bill so as to make it accomplish the purpose for which it is intended.*

**3 Medical Service for Works Progress Administration Employees**—*Under the Emergency Relief Appropriation Act of 1935, the federal government has undertaken to provide work for unemployed persons in necessitous circumstances who are physically and mentally capable of working. It has turned back to the states all unemployed persons in such circumstances who are physically or mentally unfit for work. Under the Works Progress Administration, employable persons are being employed in large numbers but at wages apparently insufficient to enable them to provide themselves and their dependents with the necessities of life including medical and hospital service, and the Works Progress Administration provides medical and hospital service only for traumatic injury in the line of duty. The result is that employees of the Works Progress Administration are often dependent on their respective states and the political units of such states and on private charity, including the charity of physicians for medical and hospital service. Until the administration pays more liberal wages there will be no relief from this situation, and physicians in accordance with the best traditions of the profession, must see that no deserving person suffers unnecessarily for lack of medical and hospital service. Medical and hospital service for unemployable persons rests in any case primarily on the state and its political subdivisions with which physicians must cooperate to work out the most effective methods of providing medical and hospital service with justice to the beneficiaries, the medical profession and the public.*

**4 Medical Service for Wards of the Rural Resettlement Administration**—*In the Rural Resettlement Administration a condition exists similar to that described as existing under the Works Progress Administration. Persons located on rural resettlement projects seem to be so limited in income as to be unable to provide medical and hospital services for themselves and their dependents. Apparently they must depend on the states, the political subdivisions of the states, and the local medical profession for medical and hospital aid, gratis or at prices*

within their reach, even while they are endeavoring to establish themselves on these federal projects, with the aid of the federal government

**5 Medical Units in Reserve Officers' Training Corps**—Medical units in the Reserve Officers' Training Corps will be reestablished if the War Department appropriation bill is accepted by the House of Representatives in the form in which it has passed the Senate

**6 Industrial Medicine in Department of Labor**—The proposed authorization of the Secretary of Labor to appoint a board to investigate the health conditions of workers employed in the construction and maintenance of public utilities, notwithstanding the effective work of the bureau of the Public Health Service in the field of industrial medicine, has now assumed the form of a proposed investigation of the subject, either by a committee of the House of Representatives or a joint committee of the Senate and the House of Representatives. The matter is now pending in both houses

**7 Reallocation of Federal Bureau of Narcotics**—The Federal Bureau of Narcotics will become a unit in a newly created Secret Service Division of the Treasury Department, if pending legislation is enacted. It will, however, retain by statute the function of supervising the legitimate traffic in narcotic drugs and certain other functions having to do with such drugs from other than criminal standpoints. The fear expressed by some that this reallocation of the Bureau of Narcotics would lead to an objectionable surveillance of physicians by secret service officials is not shared by the Board of Trustees

**8 Pensions for Contract Surgeons, Spanish-American War**—No progress has been made toward procuring for contract surgeons of the Spanish-American War pensions for disability due to age, similar to the pensions already provided for contract nurses who served in that war. Such contract surgeons, unfortunately not organized, seem to be unable to plead their own cause effectively and efforts to arouse an interest in this matter on the part of the committee of Congress before which it properly comes have proved unavailing

**9 Legislation Pertaining to Contraception**—Bills are pending in Congress to legalize the dissemination of information, preparations and devices to facilitate the prevention of conception. Other pending bills are designed to facilitate the prosecution of persons who send by mail indecent and obscene articles and contraceptive information, devices and preparations. The Association has taken no part in the activities that have been carried on for the promotion or for the defeat of such legislation

**10 Hospitalization and Medical Services for Veterans**—Enacted legislation provides for an increase in the number of beds for veterans of the World War, generally for veterans suffering from neuropsychiatric and tuberculous diseases. The program contemplates construction during the next five years to provide for 2,276 beds for general and surgical cases at existing hospitals. Three pending bills propose to provide additional hospital facilities

**11 State Health Insurance**—In seven states, bills were proposed looking toward the establishment of compulsory systems of state health insurance, but none have been enacted. Most of these bills have been patterned after the so-called Epstein bill

**12 Uniform Narcotic Drug Act**—The uniform narcotic drug act approved by the American Medical Association was adopted in 1935 in nineteen states with or without modification. It is now in force in twenty-nine states. There is a tendency to make such legislation applicable to cannabis and to include in it provisions for the commitment of addicts, which do not appear in the bill as originally drafted. Unfortunately there seems to be a tendency, too, to weaken the provisions of the bill particularly with reference to the sale of so-called exempt preparations, in a way that will tend to make those preparations more readily obtainable by narcotic addicts

Laws undertaking to regulate the sale and distribution of certain hypnotic or somnifacient drugs, notably drugs

depending for their potency on barbituric acid derivatives, were enacted in seven states. Legislation of this type is now in force in fourteen states

**13 Laws Relating to Practice of Healing Art**—Medical practice acts were amended in eleven states. A basic science law was enacted in Iowa. Osteopathic practice acts were extensively amended in Iowa and New Jersey, enlarging the rights of osteopaths

A physicians' lien law was enacted in North Carolina enabling physicians to establish liens to secure payment for services rendered persons injured by accidents for which other persons are responsible

Gunshot and other wounds were made reportable to police officials by physicians treating persons so injured in Minnesota and New Hampshire

**14 Hospital Service Corporations**—The organization of hospital service corporations to provide for hospital care for their members or subscribers was authorized in Alabama, California, Illinois and Indiana. The purpose of these corporations is to provide hospital service when necessary for periodic payments of stated amounts, made by members or subscribers in advance of the actual need

**15 Workmen's Compensation Acts**—Workmen in New York entitled to medical service under the workmen's compensation act are authorized by a recent act passed to select their own physicians, the choice being limited, however, primarily, to physicians whose names appear on rosters prepared by the industrial commission with the cooperation of county medical societies. The industrial commissioner is authorized to establish a schedule of fees for medical services. In New York provision was made for compensation for disability due to occupational diseases of any kind. In North Carolina disability due to any one of twenty-five occupational diseases was made compensable. In West Virginia disability due to silicosis was made compensable

**16 Licensing Clinical Laboratories**—Under a recently enacted California law clinical laboratories must be licensed. In Oregon a new law requires the registration and regulation of laboratories

**17 Evidence of Blood Tests Admissible**—The introduction in court in evidence of the results of certain blood tests was authorized by statute in New York and Wisconsin

**18 Animal Experimentation**—Bills for the regulation of experiments on living animals were introduced in New York, Wisconsin and California, but none were passed. Two bills are pending in Congress proposing to prohibit experiments on living dogs in the District of Columbia

**19 United States Department of Health**—In view of certain government investigations now under way looking toward the reorganization of the executive departments and offices of the federal government, one of which has particular reference to the reorganization of the health service, it is believed to be inexpedient for the American Medical Association to seek the establishment now of a United States department of health with a cabinet officer at its head

**20 Integration of Medical Profession**—No new developments have appeared concerning the integration of the medical profession. No way has been developed for the integration of all practitioners of the healing arts in such a way as would bring the cult practitioners under rational supervision and control and unless they can be incorporated in any scheme that may be developed for integration the effectiveness of integration as a means for protecting the public from incompetent practitioners is at least doubtful. This matter may well be kept under observation

**21 Free Choice of Physician by Disabled Federal Employees**—Although employees of the federal government, including employees of the Works Progress Administration are limited in their choice of physicians and hospitals to government medical officers and hospitals or physicians and hospitals recognized and approved by the United States Employees Compensation Commission, the time does not seem opportune for agitation to procure

for such employees a broader right to choose. The federal government employees themselves seem to be uninterested in the matter.

**22 Cooperation by State and County Associations—***The Bureau of Legal Medicine and Legislation has received the active support and cooperation of state and county medical societies and individual members of the Association. It cannot, however, give legal advice to individual members of the Association concerning personal legal problems. It may be questioned whether the Bureau might not with advantage limit its reply to inquiries received from correspondents—whether the members of the Association, subscribers, hospitals or others—to such inquiries as have been directed to the proper officer or officers of state associations and forwarded through such officer or officers to the Bureau.*

#### Bureau of Medical Economics

The Bureau of Medical Economics has been under a constant stress during the past year investigating economic problems, preparing reports for distribution to the medical profession and advising physicians throughout the country concerning special medical economic problems in various states. This was especially true concerning sickness insurance. During the latter part of 1934 and the first half of 1935 approximately 182,000 reprints of the Bureau of Medical Economics pertaining to sickness insurance were circulated through medical societies and individual physicians and a considerable number were sent directly to lay persons throughout the United States; this circulation was in addition to the articles published in *THE JOURNAL* and the *BULLETIN*.

#### MEDICAL SERVICE PLANS

The report of the reference committee adopted by the House of Delegates at the special session on Feb. 15 and 16, 1935, suggested that the Board of Trustees request the Bureau of Medical Economics to study further the county medical society service plans then existing and such as might develop. This study was made and the report was presented to the House of Delegates at the Atlantic City session. With but few changes suggested by the Reference Committee on Medical Economics, the report was adopted as presented.

At the time this study was made, many county medical societies had progressed in their consideration of medical service plans no further than to make a survey of their local requirements or to study the plans about to be adopted elsewhere. For this reason it was impossible to include in the report any definite pronouncements as to the success of such plans. Experience is needed to provide answers to such questions as the costs of operation, the quality of service rendered, the applicability of the plan to the locality in which it operates, the effects on the medical profession and the way in which the plan meets the community needs. It is also desirable to know whether a medical service plan constitutes the major activity of the county medical society, supported to the exclusion of other proper interests, or whether such a plan is merely a part of a well planned program of medical society activities in which all phases of medical practice and community welfare are accorded proportionate emphasis. The opinion is offered that the study of medical service plans should be continued with the object of securing as promptly and as accurately as possible answers to these questions. A study is now in progress to show all phases of county medical society activities in certain localities in which medical service plans are operating. An attempt is being made also to determine the measure of success attained by medical service plans.

#### DISTRIBUTION OF PHYSICIANS

During the past year the Bureau's publication entitled *Distribution of Physicians in the United States* has been well received by a large number of persons and organizations interested in some phase of the distribution of physicians in this country. This is the most recent attempt to show the distribution of all the physicians enumerated in the *American Medical Directory*. The most complete previous study was made by Lewis Mayers and Leonard V. Harrison in 1924 and was published by the General Education Board under the title *The Distribution of Physicians in the United States*. The study

by Mayers and Harrison is valuable for the comparisons it affords with distribution in 1923 and some previous years, chiefly 1906.

Some of the general conclusions drawn from this study are as follows:

The population per physician appears to be increasing; in 1890, according to the best available information, the population per physician was 629, whereas in 1931 it was 785.

The number of graduates in medicine is increasing steadily; the low point was reached in 1922 with 2,500 graduates; in 1931 there were 4,735 graduates and in 1935 the number had increased to 5,101. These figures suggest that the population per physician may show a downward trend for the years since 1931.

The percentage of all physicians in active practice who in 1931 were classified as limited specialists was 16.5. The largest percentage of limited specialists in a geographic subdivision of the United States, 19.8, was found in the Pacific states. The lowest percentage, 11.9, was found in the East South Central states.

The largest number of physicians classified as limited specialists were found to be practicing in diseases of the eye, ear, nose and throat. The smallest number were found in bacteriology.

A comparison of the distribution of physicians according to size of community for 1931 with a similar distribution for 1906 shows that, whereas in 1906 there were 29.5 per cent of all physicians practicing in communities of less than 1,000 population, in 1931 there were only 13.4 per cent of all physicians in communities of this size. The same tables show that in communities with a population of 100,000 and over there were 29.8 per cent of physicians in 1906 and 46.2 per cent in 1931. These figures seem to indicate a very appreciable drift of physicians away from the rural and small communities to the larger urban and metropolitan centers.

It appears that the largest percentage of physicians practicing in communities with a population of 10,000 and less are between the ages of 30 and 39 years.

The distribution of physicians by states according to population per physician compared with the average income in dollars per person indicates that as the average income per person decreases the number of persons per physician increases. These data seem to confirm the general observation that the number of physicians which can be supported by a community depends, to a large extent, on the amount of individual spendable income.

Neither of these studies constitutes a complete study of the distribution of physicians. It is proposed to assemble additional data to show the number and distribution of women physicians, Negro physicians and irregular practitioners, the distribution of physicians according to years in practice by size of community and by specialty, and the number of physicians serving in full time positions.

#### MEDICAL RELATIONS UNDER WORKMEN'S COMPENSATION

During 1935 there were several successful efforts on the part of medical societies to effect better relationships between the medical profession and various bodies dealing with or enforcing workmen's compensation statutes and regulations. In several states, statutes and regulations were changed. In 1933 the Bureau of Medical Economics published a report entitled *Medical Relations under Workmen's Compensation*. This publication has had wide distribution and use. When it became necessary to print a second edition of this report a chapter was added giving briefly the changes in workmen's compensation during 1933 and 1934 and the first half of 1935. It is proposed to revise this report periodically to include the current changes in workmen's compensation legislation and regulations.

#### CARE OF THE INDIGENT SICK

The report on the Care of the Indigent Sick was prepared and published late in 1934. In this report an attempt was made to trace the historical origin of some of the present-day problems in the medical care of the indigent and to call attention to some of the standards that should be used to determine the receipt of free medical care. At this time the federal government had assumed some responsibility in the care of the indigent through the Federal Emergency Relief Administration. In the first edition of the publication *Care of the Indigent*

Sick" the most accurate information obtainable was included to show the way in which the various states had developed plans based on federal rules and regulations to meet this emergency in cooperation with the Federal Emergency Relief Administration.

When it became necessary to issue a second edition of "Care of the Indigent Sick," the emergency medical relief measures had been complicated by rules pertaining to the Civil Works Administration, the Public Works Administration and later the Works Progress Administration. Since medical societies had not had sufficient time to develop plans or even to determine courses of action based on regulations promulgated by these later federal agencies, it was thought unwise to include in the second edition any description of medical services under the new regulations but to review them at some later period when more definite data might be obtainable.

#### UNIVERSITY AND COLLEGE STUDENT HEALTH SERVICES

Among the reports of the Committee on the Costs of Medical Care is a study of "University Student Health Services" in which the statement is made that facts are revealed which "have considerable significance in indicating certain important advantages to be gained by organization and by periodic payments for the essential elements in medical care."

A study of student health services may be divided into two phases: one an evaluation of the quality and effectiveness of service rendered and the extent to which the service meets the needs of the students, and the other a statistical study of costs, morbidity among students, extent to which students utilize the facilities of the student health service, number and classification of persons covered by the health service arrangements, the number and type of personnel engaged in providing the services, and many other important items.

It is stated in the committee's study that no attempt has been made to determine the effectiveness of the service or to ascertain the extent to which the medical care provided meets the needs of the local student body. The number of universities studied (only six universities from several hundred universities and colleges) can scarcely be accepted as sufficient to provide an amount of data from which to draw statistically reliable conclusions for student health services throughout the United States. The study may therefore be considered as merely a descriptive analysis of the health services of six universities varying in size from about 3,000 to slightly over 10,000 student population.

The Board of Trustees in 1934 requested the Bureau of Medical Economics to make a study of student health services in all the leading colleges of the United States. Accordingly the study was begun by compiling a list of colleges that maintain a student health service. The list of colleges and universities comprises institutions accredited by the Association of American Universities, member institutions of the American Student Health Association and colleges for Negroes approved by a special committee of the Division of Higher Education of the United States Bureau of Education. To these colleges and universities a schedule was sent requesting information desired for the study. Some universities were visited to observe the methods used in the operation of their health services, the type and amount of equipment, and to gather an impression of the atmosphere surrounding the student health service department. Some universities sent well prepared analyses of their services which have been very helpful.

The report of the Bureau is based on data taken from the schedules returned by 238 colleges and universities and seventeen colleges for Negroes. The subject matter of the report is arranged according to the following main headings:

##### Introduction

##### The Evolution of Student Health Services

##### The Health Program Under Student Health Services

##### The Status of Student Health Services

##### Health Services and the Medical Field

##### Summary and Evaluation

From the data available several features of student health service are apparent. (1) There has been, during the last decade, a steady increase in the number of institutions maintaining student health services. (2) there appears to be a

surprisingly large amount of capital invested in buildings and equipment devoted to health and medical services for students, (3) there seems to be a general tendency to develop health and medical services in colleges and universities on an institutional rather than a geographic basis, (4) there seems to be evidence to show that the health instruction of students—presumably the primary function of a student health service—has not always been done as well as might be expected of institutions of higher learning, (5) it is impossible to find any universally accepted measure of performance or accomplishment by which the programs and benefits of student health services may be judged, (6) it appears that a very large percentage of universities and colleges are actually engaged in the practice of medicine in varying degrees, and (7) the number of instances in which a practical cooperative arrangement has been effected between the college and the county medical society of the college community for the medical care of students seems to be lamentably small.

Each service seems to have been specially developed to satisfy the ideas and desires of those who formulate and direct the policies of each separate institution. Neither the organization nor the conduct of student health services seems to have followed any generally accepted principles or objectives except to provide students with some sort of health instruction and variable forms and degrees of medical advice and care. In some instances both the health instruction and the medical care seem to have been creditably done; in others the methods and results in both these phases of student health service appear to be questionable.

One of the most serious tendencies in student health service is the inclination to adopt the institutional method of providing medical care. If this method were to be generally accepted and adopted it would lead to almost endless confusion. On this basis it is conceivable that every social, industrial, commercial, religious, fraternal, cultural or other form of institution would be justified in developing its own special medical service. Such a method would bring with it an almost endless amount of duplication, redundancy, omission and confusion. Continuous intimate personal relations between physicians and their patients would be extremely difficult if not quite impossible to maintain. Change of employment or institutional membership would mean also a change of personal medical adviser. Institutions and not the medical profession would control and direct medical practice.

College and university students represent a select group of the population which, for several reasons, should show a low morbidity rate. Moreover, most students are associated with institutions of higher learning for only a relatively short period of their lives. One of the primary purposes for which students attend educational institutions is to acquire information. In this respect colleges and universities are entirely justified and may well be encouraged in providing facilities for health instruction. Medical advice and care are by no means synonymous with health instruction. Students are subject to many of the same forces that affect the general population and they often need medical care. It is suggested therefore from this study of available data that in the interest of good public policy as well as of good medicine, an effort be made to establish some fundamental principles that can be accepted and applied in the correct provision of medical care to this section of the population.

#### GROUP HOSPITALIZATION

The subject of group hospitalization has been commanding attention since late in 1930. While commonly thought of as any plan under which a number or group of individuals make periodic payments to a fund to enable each individual to receive hospital care when needed, it is evident that this concept must be more narrowly defined because under it can be included industrial health services, mutual benefit associations, trade union plans, university health services, fraternal or lodge plans and any type of plan under which patients are hospitalized other than in the traditional fee per patient manner. A clarified definition is not a basis for conclusions but it does point out a course of investigation.

Group hospitalization by its very name connotes that the relationship is one of direct arrangements between hospitals and groups and that hospital care alone is the service bargained for. Group hospitalization then, is a plan whereby a hospital

or an association of hospitals contracts with classified groups of people to furnish hospital care when needed in return for the periodic payment or prepayment of a stipulated sum by each member of the group. A bona fide group hospitalization plan, as defined, should exclude all professional or medical services of physicians or surgeons, pathologists, roentgenologists, anesthetists and special nurses. The control of the service provisions and membership funds should be in the hands of those who can render the service, namely, the hospitals or an association properly representative of the hospitals and the medical profession.

The first type of plan was that of a single hospital which offered specified services to groups of persons, without utilizing a sales agency, at lower rates than individuals could independently purchase similar services. The prepayment or group budgeting idea gained favor, and plans developed in many sections of the United States.

Commercial organizations, whose interest in making hospital service more available was secondary to the profits they envisioned, began promoting plans and organized and conducted membership drives. The abuses caused by commercialization and the prospective defects of group hospitalization plans were called to the attention of the medical profession, hospital administrators and the public in the report on "New Forms of Medical Practice," an outline of schemes that were being utilized to "organize" and institutionalize the practice of medicine. These defects were later emphasized by the studies entitled "Prepayment Plans for Hospital Care" and "Group Hospitalization Contracts Are Insurance Contracts," which appeared in *THE JOURNAL* during 1933.

The realization of some of the possible untoward effects of unsound and commercial plans, and the recognition that group hospitalization contracts were insurance contracts in the majority of the states, caused some modification of the utopian claims for the plan.

The nature of the contract and the type of administrative organization for hospitalization plans are of vital concern to the medical profession. The medical profession is opposed to any plan that will destroy the basic features of medical service or will permit hospitals to enter the practice of medicine. If hospitals are permitted to include medical care in their contracts for hospital service, the precedent is set for institutionalized contract medical practice with all its destructive effects on the art and science of medicine. In at least twenty communities, county or state medical societies are active in the organization and control, or have given approval after close observation, of the administration of the hospitalization plans. In many other localities the plans have at least been studied and some action taken by county or state medical societies.

The protagonists of group hospitalization have created the erroneous impression that the medical profession opposes all group hospitalization plans. Those plans offered by community-wide, noncommercial associations of hospitals, designed to offer hospital facilities to low-income groups in a manner and at a cost commensurate with knowledge gained from experience and sound advice, which have a representation of the local medical profession in the administration to assure the exclusion of features objectionable to the practice of medicine, have encountered no serious obstruction on the part of medical societies. The most encouraging progress in group hospitalization has been made by these plans.

The theory of the insurance principle in the provision of hospital service appears to be reasonable but the application of this principle introduces many inherent dangers that should not be overlooked. The determination of actuarially sound bases for premium rates, the careful selection of risks and the wise handling of funds are insurance duties that cannot be lightly undertaken by the inexperienced. The fixation of charges for all hospitalization at a level too low to be compatible with good hospital service, the solicitation of patients and the competition between hospitals with different plans, the diversion of funds to sales agencies or to profit taking corporations, the placing of undue emphasis on hospitalization and the possibility of keeping active some undesirable institutions are but a few of the objectionable features in addition to the more important dangerous tendencies that have been mentioned.

Unfortunately, there are no reliable indexes available by which to judge the value of group hospitalization. There seem to be no accurate and dependable data available concerning the cumulative experience of this new method of providing hospital facilities for the sick.

The Bureau of Medical Economics, through the Council on Medical Education and Hospitals, has instituted a survey in an attempt to analyze the experiences of group hospitalization plans and to prepare a report that may be useful to the administrators of present plans and to those who desire to organize new plans. On Jan. 1, 1936, the Bureau had compiled from various sources a list of group hospitalization plans that either had been proposed or were in operation or had been discontinued after a period of operation. A schedule was sent to each of these organizations requesting specific information as to the present status of the plan.

At the present time sixty-six schedules, approximately 46 per cent of the total sent, have been returned. The sixty-six schedules returned indicate that twenty-three plans are in operation, five have been consolidated with existing plans, four are still proposed or under consideration, four were once in operation but are now discontinued, and thirty are not now in existence, either having never existed or the schedule was returned marked "not in directory" or "moved, left no address."

Information secured from various sources seems to indicate that there were 144 plans, with 512 associated hospitals, located in 107 communities throughout thirty-two states and the District of Columbia. Definite information has been received from sixty-six plans of the remaining seventy-eight plans that have not returned their questionnaire. The Bureau has reasonably definite information concerning only thirty-one. It is believed that the remainder will prove to be either nonexistent or inactive.

Recent information has brought nineteen additional plans to our attention, seventeen are proposed and two are in operation. These plans have had no experience and were not included in the survey.

The returns to date suggest that the importance of group hospitalization plans has been overstated when measured by the actual number of plans in operation and the number of members enrolled. The returned reports also suggest that there has been only a semblance of an effort to keep records of experience or to prepare accurate financial statements, and it has been difficult to find sufficient actuarial data on which to base sound premium rates. Although group hospitalization properly organized and operated may in some communities serve to supplement existing medical facilities, the plan must not be considered a panacea for the medical economic ills of a community, and extreme caution must be exercised if many of the evils and destructive elements that have attended other new forms of medical practice are to be avoided in these undertakings. When all plans that have had any experience return their schedules, a report of the results will be completed.

#### RELATION OF MEDICAL ETHICS AND MEDICAL ECONOMICS

Practically all economic transactions involve an ethical implication good or bad. Many of the principles of medical ethics carry some economic implication.

Since ethics and economics seem to have a definite relationship, an endeavor has been made to set forth these relations in a report entitled "Economics and the Ethics of Medicine."

This report begins with a discussion of the ethics and economics of industry, business and commerce. This chapter is followed by an analysis of the Oath of Hippocrates, with some reference to the similarity of the wording of the oath in the Greek, Arabic, Latin and East Indian. The development of medical ethics is then traced in modern times. A chapter is devoted to the medical group and the influence which ethical principles have exercised in cementing and maintaining physicians in an organized group.

The remainder of the report is devoted to an examination of the economic implications in the Principles of Ethics of the American Medical Association.

#### DEBATE ON STATE MEDICINE

In March 1935 the National University Extension Association Debate Committee announced the national debate subject for 1935-1936. The proposition is *Resolved*, That the several states

should enact legislation providing for a system of complete medical service available to all citizens at public expense. It is estimated that this proposition will be debated by more than 100,000 students in high schools, colleges and universities throughout the United States during the present school year. The debaters will be heard by large and small audiences, in auditoriums and over the radio. Already a considerable amount of public interest has been stimulated over this activity.

In May 1935 Mr Bower Aly, editor of the Debate Handbook of the National University Extension Association Debate Committee, requested that an article supporting the negative of the debate proposition be prepared for the handbook. At the same time Mr Aly requested that publications of the Bureau of Medical Economics be made available to the members of debating teams.

An article entitled "The Medical Profession Is the Only Competent Judge of Medical Services" was prepared by the Bureau and appears on pages 113-136 of volume I of the Ninth Annual Debate Handbook, entitled "Socialized Medicine." Publications of the Bureau of Medical Economics were divided into two groups for members of debating teams. One group consisting of four reprints—Some Defects in Insurance Propaganda, A Critical Analysis of Sickness Insurance, Sickness Insurance Not the Remedy, and Sickness Insurance Catechism—was offered for free distribution to individual debaters. The other group, consisting of fourteen reprints listed as follows, was offered as a library package to be lent to debaters by the debate coach of the school.

An Introduction to Medical Economics  
Handbook of Sickness Insurance  
State Medicine and the Cost of Medical Care  
Collecting Medical Fees  
Contract Practice  
Income from Medical Practice (with supplement)  
Some Phases of Contract Practice  
Medical Relations Under Workmen's Compensation

Group Practice  
New Forms of Medical Practice  
Health Insurance in England and Medical Society Plans in the United States  
Prepayment Plans for Hospital Care  
Group Hospitalization Contracts  
Distribution of Physicians in the United States  
Care of the Indigent

Mr Aly designated thirty-two points of distribution among the educational institutions of thirty states. Subsequently several state medical societies assisted in the distribution of the debate material. Several state medical societies have prepared an outline of arguments against state medicine.

The National University Extension Debate Committee arranged a radio debate on the national debate proposition. This was presented over the Red Network of the National Broadcasting Company, Nov 12, 1935. The speakers for the affirmative were Mr William T Foster and Mr Bower Aly, and for the negative Dr Morris Fishbein and Dr R G Leland. This debate was taken on phonograph records made at the time and is now available in reprint form.

Between the dates of March 1935 and Jan 1, 1936, approximately 134,000 reprints of the Bureau of Medical Economics were distributed for the use of students on debate teams. Only a comparatively small number of debates were held up to Jan 1, 1936. The reports that have been received indicate that the negative teams have won in most instances.

A considerable number of county medical societies and individual physicians have requested reprints of the Bureau and other statistical data on state medicine and have used this material in assisting members of debate teams in preparing their negative arguments.

#### Summary

*The activities of the Bureau of Medical Economics for the year 1935 may be summarized under the following headings:*

**Sickness Insurance** Continued study of the subject collection of reports of foreign systems, statistical data and comparison of vital statistics under these systems with nearly comparable statistics in the United States where possible, preparation of statements setting forth the characteristics of sickness insurance and distribution of reports and specially prepared articles on sickness insurance.

**Medical Service Plans** Continued study of county medical society plans, criticism of proposed plans, collection of data and descriptive material to show well planned and balanced county medical society programs

and the relative emphasis given to medical service plans, an effort to determine the measure of success attained by medical service plans in serving sick people.

**Distribution of Physicians in the United States** A study with fifty-four tables and fifteen charts to show, in part, the distribution of physicians according to population, type of practice, age and geographic location of the physicians listed in the 1931 American Medical Directory.

**Medical Relations Under Workmen's Compensation** Revision of the original report on this subject to include the changes in workmen's compensation laws and relations that were made in 1933, 1934 and the first half of 1935.

**Care of the Indigent Sick** Comment and suggestions offered on plans for the medical care of the indigent proposed by county and state medical societies.

**University and College Student Health Service** Completion of a study of University and College Student Health Service requested by the Board of Trustees in 1934 with summary and conclusions.

**Group Hospitalization** Attempt to define the term "group hospitalization", compilation of list of group hospitalization organizations, collection of data pertaining to the experience of this new method of providing hospital facilities for the sick, criticism of proposed plans and advice concerning the attitude of the American Medical Association toward such plans.

**Relation of Medical Ethics and Medical Economics** A report nearly completed which endeavors to show the economic implications in the Principles of Medical Ethics and a discussion of the ethical applications of the principles of medical economics.

**Debate on State Medicine** Preparation of special article for the official handbook of the National University Extension Association Debate Committee, distribution of publications of the Bureau of Medical Economics to medical societies, individual physicians, student debating teams university extension departments and high school, college and public libraries.

**General Travel** forty visits to thirty-three cities in eighteen states and the District of Columbia covering a total distance of 38,610 miles. Speaking engagements and conferences seventy-eight addresses and conferences with an attendance of 7,900, mostly physicians. Correspondence 3,263 communications.

#### Proposed Program

1 Continued study of state managed medical systems of foreign countries and preparation of data and reports for the use of the medical profession.

2 A study of medical service plans to determine, if possible, the measure of success they have attained in making medical services more easily available to the people of low incomes.

3 Compilation of additional data on distribution of physicians in the United States and in foreign countries.

4 Preparation of new material to be used in revisions of the publications "Medical Relations Under Workmen's Compensation" and "Care of the Indigent Sick."

5 Completion of study now in progress on group hospitalization.

6 Revision of publication "Collecting Medical Fees."

7 A study of rural medical facilities.

8 Cooperation with Council on Medical Education and Hospitals in furnishing material and suggestions to medical schools on the instruction of medical students in medical economics.

#### Bureau of Health and Public Instruction

Because of the increased demands made on the Bureau of Health and Public Instruction, it was necessary to increase the personnel of the Bureau through the employment of an assistant director and an additional stenographer. Dr P A Teschner

a member of the State Medical Society of Wisconsin, assumed his duties as assistant director, Dec 16, 1935. He has had much experience in the field of health education.

#### RADIO PROGRAM

A very radical change has been made in the character of the radio program which was instituted over the Blue Network of the National Broadcasting Company in 1933 in that the program now consists of radio dramatizations, broadcast weekly over the Red Network. Subjects of popular interest have been selected for this program including automobile accidents, household emergencies, hunting accidents, animal disease in man, asphyxiation, burns and others which have lent themselves to dramatization and about which the public needs to be informed. These programs have been well received throughout the United States, and a number of commendatory expressions concerning them have come from England and other countries, where the programs have been heard by means of short-wave reception. No effort has been spared by the National Broadcasting Company in putting this program on the air in a first class manner. Officers and members of the official personnel of the National Broadcasting Company have taken enthusiastic interest and have given the greatest possible assistance to insure the success of the program. The Board of Trustees and the Bureau of Health and Public Instruction offer an expression of grateful appreciation to the major officers of the National Broadcasting Company who have exhibited a personal interest, and to Miss Judith Waller, educational director, to Mr. Lawrence Holcomb and Mr. Theodore Scherdmann of the production department, to Mr. Charles Lyon, the announcer, and to Mr. William J. Murphy, who has prepared the scripts, which have been notable for human interest, dramatic intensity and scientific accuracy. All the talks in connection with the dramatizations have been delivered by Dr. Morris Fishbein, editor, Dr. W. W. Bauer, director of the Bureau of Health and Public Instruction, and Dr. R. G. Leland, director of the Bureau of Medical Economics.

A radio library for the use of local medical societies is being maintained and now contains 766 talks. During the year, 4,780 items from this radio library were distributed for the use of fifty-four component county medical societies and fourteen constituent state medical associations.

#### CORRESPONDENCE AND QUESTIONS AND ANSWERS

The direct correspondence of the Bureau has increased by more than 60 per cent within three years. Approximately 11,000 letters were written during the year 1935.

The question and answer correspondence showed an increase during the year of approximately 11 per cent. In certain instances queries and answers are published in *HYGEIA*, but there is a constant diminution in the percentage of the number so published.

#### COOPERATION WITH STATE AND COUNTY MEDICAL SOCIETIES

In an effort to be helpful to component county medical societies, the Bureau has maintained the fullest possible contact with the officers of these organizations. Social security legislation has apparently been the subject of greatest interest to county and state medical societies. With members of the Board of Trustees and with the director of the Bureau of Medical Economics, the director of the Bureau of Health and Public Instruction attended a conference of state and territorial health officers with the United States Public Health Service and the Children's Bureau held in Washington, D. C., when the implications of the social security bill then pending were fully discussed. The sessions of the Conference of State and Provincial Health Authorities in Atlantic City were attended by the chairman of the Board of Trustees, the director of this bureau and the director of the Bureau of Medical Economics. Information obtained at this conference has been made available to the medical profession through correspondence through articles published in the *AMERICAN MEDICAL ASSOCIATION BULLETIN* and through personal conferences.

The director of the Bureau was authorized by the Board of Trustees to accept membership on the General Advisory Committee to the United States Children's Bureau and attended a meeting of that committee and of its subcommittee on maternal and child health services in Washington in December.

#### COOPERATION WITH GOVERNMENT AGENCIES AND WITH LAY ORGANIZATIONS

The director of the Bureau of Health and Public Instruction and Dr. Arthur J. Cramp, formerly director of the Bureau of Investigation, attended a hearing before the Federal Communications Commission and presented the points of view of the American Medical Association with respect to radio advertising and freedom of expression on the air.

By order of the Board of Trustees, the director of the Bureau continues to serve as a member of advisory committees of the following organizations: National Congress of Parents and Teachers, General Federation of Women's Clubs, Joint Committee on Health Problems in Education, and the National Committee for Boys and Girls Club Work. The director of the Bureau was also authorized by the Board of Trustees to participate in the official activities of the American Public Health Association and, at the 1935 annual meeting of that organization in Milwaukee, was elected chairman of the Section on Health Education.

#### FIELD WORK

During the year 1935 the director of the Bureau delivered eighty-six addresses and attended twenty conferences and meetings. The audiences addressed included 518 physicians in the medical society groups, approximately 20,000 persons in lay groups and about 3,000 persons in groups including both physicians and nonmedical listeners. A number of appearances were made before high school audiences. One hundred and eight days were spent in the field.

#### PAMPHLETS AND REPRINTS

Eight of the pamphlets prepared under the auspices of the Bureau of Health and Public Instruction were revised and reprinted during the year, eight pamphlets were discontinued and fourteen new pamphlets were added to the catalogue.

#### OTHER ACTIVITIES

The Bureau of Health and Public Instruction has cooperated as fully as possible with the editorial department and has prepared material for *HYGEIA* and the *AMERICAN MEDICAL ASSOCIATION BULLETIN*. Nine articles prepared by the Bureau were published elsewhere than in the Association's periodicals. The Bureau has also cooperated with the Bureau of Exhibits in connection with service to local and state medical societies and to other important groups.

#### Summary

*Dr. P. A. Teschner of Milwaukee was appointed assistant director of the Bureau of Health and Public Instruction, Dec 16, 1935.*

*There has been considerable expansion in the scope of the Bureau's work including greatly increased correspondence and more extensive activities in the field.*

*The Association's radio program, under the immediate direction of this bureau, has been received with great favor throughout the United States and has been commended in several foreign countries.*

*The Bureau has attempted to maintain helpful contact with important national organizations and official agencies of the federal government.*

*The director is serving as a member of advisory committees of several important organizations of national scope.*

#### Bureau of Investigation

Dr. Arthur J. Cramp, director of the Bureau of Investigation after nearly thirty years of service characterized by the utmost devotion, loyalty and efficiency, was compelled to retire Nov. 30, 1935, because of the condition of his health. The department now known as the Bureau of Investigation and formerly called the Propaganda for Reform Department was developed by Dr. Cramp who gave himself entirely to its work in the interests of scientific medicine and for the protection of the public. With no thought of self and with the utmost devotion to the cause he so faithfully served, Dr. Cramp fought fearlessly for the establishment of truth and for the destruction of fraud and quackery. The Board of Trustees desires to acknowledge its most sincere appreciation of the fine service.

rendered by Dr Cramp and to express the hope that he will enjoy a long period of well earned rest

Dr Frank J Clancy, a member of the Washington State Medical Association, was appointed director of the Bureau of Investigation and assumed his duties in that capacity, Feb 1, 1936

#### WORK OF THE BUREAU

The work of the Bureau of Investigation was conducted along the same well established lines that have been followed in previous years. A most important part of this work has been concerned with direct inquiries received from physicians and laymen. From ten to twelve thousand individual communications are answered by this bureau each year. The number of inquiries received from laymen is constantly increasing.

It is gratifying to note the increasing number of communications received from publishers of lay periodicals and from managers of radio broadcasting stations submitting inquiries with regard to advertising material that has been offered for publication or for broadcasting. It is also gratifying to the Board of Trustees to report an increasing number of inquiries received by the Bureau of Investigation from teachers and from the members of classes in educational institutions, indicating a growing interest in the study of the nostrum evil and of quackery.

The Bureau has continued its efforts to give such assistance as it could offer to various agencies of the federal government, including the Federal Trade Commission, the Food and Drug Administration, the Federal Communications Commission, the Postoffice Department and the Federal Bureau of Investigation. The Bureau has continued to cooperate as fully as possible with better business bureaus throughout the country.

Because of the ill health of the director of the Bureau, the amount of field work in 1935 was greatly curtailed.

Lantern slides, film strips with projector, and educational posters prepared by the Bureau have been made available to physicians and educators, and the number of requests for the use of such material has increased appreciably. The demand for the pamphlets prepared and issued by the Bureau of Investigation was strongly maintained during the year covered by this report. A third volume of Nostrums and Quackery is now in process of preparation under the immediate direction of Dr Arthur J Cramp.

#### Summary

*Dr Arthur J Cramp, director of the Bureau of Investigation, after nearly thirty years of continuous service, retired, Nov 30, 1935, because of ill health. Dr Frank J Clancy of Seattle, Washington, was made director of the Bureau, Feb 1, 1936.*

*The work of the Bureau of Investigation has been continued in increasing amount along the well established lines followed in previous years. There seems to be an increasing interest on the part of the general public in the study of nostrums and quackery, especially in educational institutions.*

#### Bureau of Exhibits

##### THE ANNUAL SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Atlantic City session was characterized not only by its size, which was the greatest in the history of the Association, but by the wide range of topics covered and the excellence of presentation by the 466 individuals who contributed material. There were 214 different exhibits, of which eighteen came from Canada. At the Cleveland session in 1934 there were 167 exhibits, while at Milwaukee in 1933 there were 120 exhibits. In spite of the commodious hall available at Atlantic City nearly 30 per cent of the applications for space could not be accommodated.

There were four special exhibits subsidized by the Board of Trustees on diabetes, nutrition, prevention of asphyxial deaths, and vaccines and serums. The appreciation of the Committee on Scientific Exhibit goes to the numerous persons who are ably assisted in these exhibits.

Several of the section exhibits committees presented special features. Exhibit symposiums were conducted on cancer, syphilis, tuberculosis, and acute infections of the central nervous

system in children. Special exhibits were given on "treatment of obstetric and gynecologic hemorrhage" and on the "relation of psychiatry to the physician in general practice." Motion picture programs were shown under the auspices of five of the sections, these pictures, together with those shown in individual booths, made a total of nearly a hundred different motion pictures shown in the Scientific Exhibit.

The Committee on Awards was confronted by an unusually difficult task, on which it worked tirelessly, presenting a report which received unanimous commendation. A total of twenty-nine awards were made, of which the Canadians received four.

#### ASSOCIATION EXHIBITS

Exhibit material has been sent out from Association headquarters on ninety-two occasions during the year to meetings in twenty-nine states. This includes both medical societies and public expositions which have been approved by medical societies. There has been collected by the Association some thirty exhibits suitable for medical and other professional groups and twenty exhibits for fairs, expositions and lay groups. The demand for exhibit material bids fair to exceed the capacity of the Bureau. There is serious doubt that expansion should be made to an extent that would enable the Association to meet all demands. The facilities of the Bureau have been greatly increased, only further to stimulate demand for its service. There is a limit established by costs of material and its preparation and by costs of transportation and breakage, beyond which the Bureau can hardly go.

In several states, notably California, Ohio and Washington, the state medical association has borrowed material for a period of months, sending it from place to place as required.

Cooperating with the California Medical Association, the Bureau has installed an exhibit at the San Diego exposition.

#### THE CENTRAL SCIENTIFIC EXHIBIT

The Central Scientific Exhibit was dismantled at the headquarters building of the Association in 1934 because of lack of space. The Museum of Science and Industry in Chicago has stored the material pending such time as it can be accommodated in that building. Installation will not take place until the latter part of 1936 in all probability.

#### MOTION PICTURES

There are many hundreds of requests annually for motion pictures and lantern slides which cannot be filled by the Bureau. The few films which the Association has available are for medical audiences and are confined mostly to the field of physical therapy. The provision and handling of films for lending purposes involves relatively large expenditures. Damages and replacements are costly and, in many instances, films are rapidly outdated.

#### Summary

*The Scientific Exhibit at the Atlantic City session was the largest and most varied that has ever been made.*

*In 1935 exhibits were made on ninety-two occasions in twenty-nine states.*

*The demand for exhibit material is fast becoming greater than can be met.*

*Cooperating with the California Medical Association, the Bureau has installed an exhibit at the San Diego exposition.*

*It is not possible for the Bureau to comply with the hundreds of requests received for motion pictures, because of costs involved.*

#### Committee on Foods, 1935

At the close of 1935 the number of products standing accepted by the Committee on Foods had reached the total of 2,893. The number of pending submissions has been so great that it was decided in April at the seventh annual meeting of the Committee on Foods that new submissions be limited for a period of six months to those of special interest to physicians. This ruling was made in order that the office of the Committee might catch up with the work of considering both new and old products.

## INQUIRIES RECEIVED

The prestige of the Committee on Foods is perhaps indicated by the large number of inquiries regarding food products which are received and answered throughout the year. The tabulated summary of the number of such inquiries received and answered by the office during 1935 follows:

Physicians	232
Health officers	19
Other professional persons	101
Medical societies and hospitals	34
Government departments	18
Better business bureaus	17
Schools and colleges	148
Food manufacturers	366
General public	717

These miscellaneous inquiries regarding food and nutrition thus average better than five a day.

## RULES AND REGULATIONS OF THE COMMITTEE

During the year the Committee found it expedient to amend several rules. In the interest of physicians and for the benefit of the public the 'Rules Governing Package Label and Advertising' have been amended by the addition of a second sentence, making the subsection read:

Names of diseases shall not be used on the package label or in advertising addressed to the public except in statements regarding nutritional disorders arising from inadequacy of the diet in nutritional essentials. Symptoms of disease shall not be referred to in lay advertising. [This statement is now in press for publication in THE JOURNAL.]

To the ruling on Violations was added the following:

No food product or class of food products or advertising therefor will be accepted or if accepted will be retained if in the opinion of the Committee such acceptance is likely to be construed as an acceptance or approval of any other products or activities of a firm when such other products or activities of such firm are in conflict with the policies of the American Medical Association as set forth in the rules of the Committee on Foods or those of the Council on Pharmacy and Chemistry or of the Council on Physical Therapy. [THE JOURNAL June 1 1935 p 1999.]

The "Rules Governing Use of the Seal" were amplified slightly in the interest of clarity.

## GENERAL COMMITTEE DECISIONS

Three new General Committee Decisions were adopted during the year and published in THE JOURNAL.

Advertising Dealing with Treatment of Disease or the Nutrition of the Sick, or Recommending any Special Type of Diet. [Feb 2 1935, p 398.]

Fortification of Foods other than Dietary Staples with Vitamin D. [Feb 16, 1935 p 563.]

Fresh Compressed Yeast, Dried Yeast and Yeast Extracts are Special Purpose Foods. [This decision is now in press for publication in THE JOURNAL.]

In addition an amendment to the Decision "Vitamin E Claims for Public Advertising" (not yet published) was adopted.

## COOPERATIVE COMMITTEE ON VITAMINS

An important development during the year was the formation of the Cooperative Committee on Vitamins of the Council on Pharmacy and Chemistry and the Committee on Foods. Members of this joint committee met in Chicago in October 1935 and discussed some of the vexatious problems concerning vitamins. The work of this cooperative committee is described more fully in the report of the Council on Pharmacy and Chemistry. An important question discussed at this meeting, and a question which is being considered by the Committee on Foods at present, concerns the vitamin D fortification of milk and cereal products.

## CHANGES IN THE COMMITTEE AND THE OFFICE

It is a sad duty of the secretary to note the loss by death of the vice chairman, Dr Lafayette B Mendel in December 1935. Dr Mendel served the Committee with distinction since its beginning five years ago, and the loss of his wise counsel is most severe. No other change in the membership of the Committee occurred during 1935.

Mr Raymond Hertzog, who acted as secretary during the formative years of the Committee, terminated his connection with the Association on Dec 31, 1935. Since that time the necessary rearrangements, to coordinate the work of the office of the Committee with that of the Council on Pharmacy and Chemistry and the Council on Physical Therapy, have begun.

The present organization of the office consists of the new secretary of the Committee, Dr Franklin C Bing, who assumed

his duties Feb 1, 1936, a secretary and five office assistants. In April 1935 Dr Ruth Cowan Clouse was appointed assistant to the secretary of the Committee on Foods to fill a long felt need for a technically trained individual to aid in the constructive work of the Committee. Unfortunately, Dr Clouse became ill in November and is now on an indefinite leave of absence.

During the past year a number of authorities in their respective scientific fields were consulted on questions of moment before the Committee arising out of its regular business. In recognition of the helpful cooperation and valuable assistance given, the Committee has voted to express publicly its appreciation by publishing the names of those who in this manner and without remuneration have gladly contributed of their time, experience and knowledge to the benefit of the Committee in its public welfare and health work.

The Committee is officially thanking the following, who have served as consultants:

Prof W E Anderson, Department of Physiological Chemistry, Yale University.

Dr H J Fisher, Connecticut Agricultural Experiment Station, New Haven, Conn.

Genevieve Stearns, Ph.D., research associate professor, department of Pediatrics, State University of Iowa.

Dr Daniel C. Darrow, assistant professor of Pediatrics, Yale University School of Medicine.

Dr Martha M. Eliot, assistant chief, U.S. Children's Bureau, lecturer in clinical pediatrics, Yale University School of Medicine.

Dr Dwight L. Wilbur, assistant professor of Medicine, Mayo Foundation.

Miss Mary A. Foley, assistant professor of Medicine (dietitian), Mayo Foundation.

Prof Henry C. Sherman, head of Department of Chemistry, Columbia University.

Prof Grace MacLeod, professor of nutrition, Teachers College, Columbia University.

## Summary

*The consideration of new submissions was halted temporarily for several months as it became more and more evident that the facilities of the office would not permit the amount of policing over advertising of accepted products that such material seems to demand. That claims opposed to the principles of the American Medical Association are promulgated from time to time is only too evident, but much objectionable material is eliminated, and the Committee during 1935 continued its efforts in this direction.*

*The Committee lost by death its vice chairman, Dr Lafayette B. Mendel, who had been a member of the Committee since its beginning.*

*Important developments of the year include an initiation of efforts to produce constructive reports for publication in The Journal, as planned by the Joint Committee on Vitamins. This subcommittee marks the beginning also of unification of the work of the Committee on Foods with phases of the work of the Council on Pharmacy and Chemistry.*

*With these beginnings, the Committee anticipates further developments leading toward completion of the plans to coordinate its efforts with similar endeavors of other departments at headquarters.*

## Requests for a Special Session of the House of Delegates

In a communication received from the Board of Trustees of the Medical Society of New Jersey, the Board of Trustees of the American Medical Association was requested to call a special meeting of the House of Delegates to be held in January or February 1936 for the purpose of discussing medical economics. Later, similar requests were received from the Medical Society of the District of Columbia, the Council of the Maine Medical Association, the Council of the South Carolina Medical Association, the Council of the Hawaiian Territorial Medical Association and the Executive Committee of the Louisiana State Medical Society. It is the understanding of the Board of Trustees that the communication from the Medical Society of New Jersey was sent to the secretaries or other officers of all constituent medical associations.

The requests submitted from official bodies of six constituent associations were given most careful consideration. In view of the fact that the By-Laws of the American Medical Association

tion specifically provide that special sessions may be called by the Speaker on written request of twenty-five or more delegates representing one third of the constituent associations or on request of a majority of the Board of Trustees, that no delegates had asked that a special session of the House of Delegates be held, that a special meeting of the House of Delegates was held in February 1935, and that the regular session of the Association would be held in May 1936, the members of the Board of Trustees felt that it would be inexpedient to ask that a special session of the House of Delegates be called to convene at any time prior to the regular session

#### Resolution Concerning the Establishment of a National Department of Health

A resolution introduced at the special session of the House of Delegates in February 1935 by Dr C E Humston of Illinois was referred to the Board of Trustees and received careful attention

The Board of Trustees was informed that a committee of the federal government has been appointed to study proposed plans for correlating the work of various departments concerned with medical and public health affairs. So far as the Board of Trustees is advised, this committee has not submitted any proposals or complaints. Having in mind the fact that some years ago a special committee appointed by the House of Delegates had thoroughly investigated a similar proposal and apparently had come to the conclusion that it would not be desirable to support plans for the establishment of a national department of health, and for other reasons which were brought out in the discussion of the general subject, the Board of Trustees did not feel that it would be wise to submit any recommendation to the House of Delegates at this time

#### Instruction in Medical Schools Regarding Organized Medicine

The resolutions submitted below were adopted by the House of Delegates of the Ohio State Medical Association and officially referred to the Board of Trustees. Similar resolutions adopted by the Council of the Arkansas Medical Society were also submitted to the Board

These resolutions are brought to the attention of the House of Delegates for official consideration

WHEREAS, It has been noted with disappointment that some of the graduates of medical schools and colleges in recent years apparently are unfamiliar with the objectives and activities of organized medicine and lack a clear understanding of the benefits to be derived through membership in local, state and national medical societies. Be it

Resolved By the House of Delegates of the Ohio State Medical Association Oct 24 1935, that the administrative officials of all accredited American medical colleges be respectfully requested to provide instruction for senior students on the activities, services and benefits of organized medicine. Be it

Resolved That a copy of this resolution be transmitted to the dean of each of the accredited medical colleges of America the Council on Medical Education and Hospitals and the Board of Trustees of the American Medical Association and the secretary of each constituent state medical society

#### Resolution Pertaining to Scarlet Fever Patent

A resolution submitted to the House of Delegates at the Atlantic City session by Dr J M Birnie, delegate from Massachusetts, was referred to the Board of Trustees

A special committee was appointed to investigate the matters with which this resolution was concerned and the subject of medical patents in general. The Board of Trustees is informed that a similar study is being prosecuted under other auspices

Because of the complexity of the existing situation with respect to medical patents and because of the scope of necessary investigations, the Board of Trustees is not prepared to submit a definite recommendation to the House of Delegates at the present time

#### Resolutions Pertaining to Pure Food Bill and to Advertising

At the Atlantic City session Dr John F Hagerty, delegate from New Jersey, submitted resolutions adopted by the Board of Trustees of the Medical Society of New Jersey requesting the House of Delegates of the American Medical Association to express its opposition to the passage of Senate Bill No 5, generally known as the Copeland Pure Food Bill, and to urge

a congressional investigation of the enforcement of the present Food and Drugs Act and further requesting the American Medical Association to refuse advertisements for any medical journal controlled by the Association or by the constituent state medical associations which are offered by pharmaceutical houses that advertise to the laity. These resolutions were referred to the Board of Trustees and have received thorough consideration

The Board of Trustees desires to inform the House of Delegates that most intensive effort was made, from the moment it became known that a new food and drug bill would be submitted to Congress, to secure the enactment of a reasonable and effective law. The Association has been represented at hearings held before committees of Congress, and many conferences have been held with members of Congress in charge of food and drug legislation and with representatives of government departments and of organizations of national scope. The Council on Pharmacy and Chemistry and the Committee on Foods made careful studies of pending food and drug legislation and prepared official reports, which were approved by the Board of Trustees and published in THE JOURNAL. Discussion of pending food and drug legislation has been presented in editorials and in special articles in THE JOURNAL

For many years the American Medical Association has been persistently active not only in its efforts to secure effective food and drug legislation but also in its efforts to secure efficient and effective administration of food and drug laws. Councils, bureaus and departments of the Association have given the utmost possible cooperation to the Food and Drug Division of the Department of Agriculture and to other governmental agencies concerned with the administration of federal statutes

In connection with this matter, the Board of Trustees has had before it a letter addressed to the chairman and members of the Federal Trade Commission by Marcus W Newcomb, M D, president of the Medical Society of New Jersey, to which were attached a copy of resolutions adopted by the Medical Society of New Jersey and a copy of resolutions adopted by the Board of Trustees of the Medical Society of New Jersey pertaining to the food and drug law, to the advertising of drugs and drug products to the laity and to "the use of the AMA endorsement in lay press and radio programs advertising food products by manufacturers of such articles." In the letter addressed by the president of the Medical Society of New Jersey to the chairman and members of the Federal Trade Commission, it was stated that certain products, including canned tuna fish, butter and "a digitalis medicinal preparation," were the subjects of applications for complaint filed with the subcommittee of the House of Representatives, and that these products displayed the seal of the Committee on Foods or of the Council on Pharmacy and Chemistry of the American Medical Association "despite officially recorded libel actions under the Federal Food and Drugs Act for adulteration or misbranding against those same manufacturers' products." The Board of Trustees is informed that this statement is misleading and unfair and, so far as is known to the Board of Trustees, was made without any effort to discover the facts from the Council on Pharmacy and Chemistry or from the Committee on Foods. The Board of Trustees is informed that the butter referred to in Dr Newcomb's letter to the Federal Trade Commission did not bear the seal of the Committee on Foods but that it was a bulk product which does not come within the consideration of that committee. The Board of Trustees is further informed that as soon as it became known that a notice of judgment had been issued as the result of a seizure by the Food and Drug Division of a small lot of a certain digitalis preparation, the Council on Pharmacy and Chemistry purchased in the open market, at places located in different sections of the United States, samples of this particular product, which were submitted to laboratory examination and were found to be quite up to required standards

In the preamble to the resolutions attached to the letter of the president of the Medical Society of New Jersey, the statement is made that the Committee on Foods, the Council on Pharmacy and Chemistry and the "Investigations Bureau" of the American Medical Association "have exercised selections unwarrantably in the notices of judgment that they have published and have permitted the license to use their seal on the advertisements of

products that are even at the same time being successfully prosecuted by libel actions under the Food and Drug Law." The Board of Trustees is informed that the implications in this statement are unwarranted. Official records of the Council on Pharmacy and Chemistry and of the Committee on Foods are available to the members of the House of Delegates.

In this connection, the Board of Trustees has also had before it a copy of the publication called the "Journal of Intravenous Therapy," apparently the house organ of a concern known as the Looser Laboratory, containing a libelous article, and a part of the preamble to the resolutions adopted by the Medical Society of New Jersey appears. The Board of Trustees is informed that these resolutions were sent to members of Congress from New Jersey, to the Secretary of Agriculture, to the Secretary of the Treasury and to the secretaries of all constituent medical associations as well as to the editors of daily newspapers in New York, Philadelphia, Atlantic City, N. J., and other cities in New Jersey.

With respect to the second part of the resolutions submitted to the House of Delegates by Dr. Hagerty, the Reference Committee on Legislation and Public Relations reported as follows at the Atlantic City session:

With reference to the resolution offered by Dr. John F. Hagerty on behalf of the Medical Society of the State of New Jersey relative to advertising your committee recognizes the danger inherent in the advertising of drugs and drug products to the laity. It sees difficulty however in the way of compliance with the request for the refusal, by the American Medical Association and its constituent state associations of all advertising whatsoever offered by pharmaceutical houses that offend against this principle for publication in the journals controlled by the American Medical Association and its constituent associations.

The committee recommends that this matter be referred to the Board of Trustees for appropriate action.

The publications of the American Medical Association are published under the direction of the Board of Trustees, but the Board does not control the advertising columns of the official journals of constituent associations. The Board of Trustees is heartily in sympathy with the attitude of the Medical Society of New Jersey so far as it applies to the advertising of drugs and drug products that should be administered at the direction of physicians.

The Official Rules of the Council on Pharmacy and Chemistry bearing on this matter are as follows:

**Rule 3—DIRECT ADVERTISING.**—No article that is advertised to the public will be accepted or retained, but this rule shall not apply to (a) disinfectants, germicides and antiseptics, provided the advertising is limited to conservative recommendations for their use as prophylactic applications to superficial cuts and abrasions of the skin and to the mucous surfaces of the mouth, pharynx and nose (but not to those of the eye, and the gastrointestinal and genito-urinary tracts) and provided they are not advertised as curative agents (see comments to Rule 3), (b) liquid petrolatum and simple preparations of liquid petrolatum, agar and simple preparations of agar, and similar preparations which act because of their bulk provided that such lay advertising carries a warning that agar and similar preparations may be harmful in colitis, (c) other agents about which the public should be informed which would not lead to harmful self-medication provided (1) they are not advertised as curative agents and provided (2) that advertising to the public does not go beyond that passed by the Council for physicians (Rule 6).

In the "Explanatory Comments on the Rules" prepared and issued by the Council the comment pertaining to Rule 3 is as follows:

**Rule 3—DIRECT ADVERTISING.**—The impossibility of controlling the irresponsible claims which are usually made in advertisements to the public, the well known dangers of suggesting by descriptions of symptoms to the minds of the people that they are suffering from the many diseases described, the dangers of the unconscious and innocent formation of a drug habit, and the evils of harmful self-medication including the dangers of the spread of many infectious and contagious diseases when hidden from the physician, and similar well-known considerations, are the reasons for discouraging, in the interest, and for the safety, of the public this reprehensible form of exploitation. Advertising in medical journals and other publications distributed solely to physicians or in journals for dentists, pharmacists, nurses

and veterinarians does not come within the scope of this rule, provided such advertising does not invite or encourage use by unqualified persons.

In the case of subjects on which the public should be instructed, as the use of certain disinfectants, germicides, antiseptics, certain laxatives, and such other articles as the Council may specify, advertisements to the public, if not in objectionable forms, are considered admissible. In no case shall such advertisements include recommendations for use as curative agents, nor shall the names of any diseases appear on or in the trade package except in connection with prophylactic recommendations. If the preparation is sufficiently toxic to require caution in its use to prevent poisoning, this fact shall be stated on the label. On account of the deplorable results which would follow any abuse of this privilege, the conscientious cooperation of manufacturers and their agents in adhering strictly to the limitations laid down is asked, and for the same reason the acceptance of an article which is so advertised as to infringe on these limitations in any essential way (as by naming diseases or by making false and exaggerated claims) shall be summarily rescinded, and the reasons for such action may be published without notice to manufacturer or agent. A disinfectant, germicide or antiseptic will be accepted for description in New and Nonofficial Remedies, and an article of this class which has already been accepted will continue to be included in New and Nonofficial Remedies only on the explicit understanding by the manufacturer and agent that such infringements of the rule will be followed by deletion of the article and by publication of the facts as described.

Respectfully submitted

ROCK SLEYSTTR, Chairman  
AUSTIN A. HAYDEN, Secretary  
JAMES R. BLOSS

## ADDENDA TO REPORT OF BOARD OF TRUSTEES

### COMMITTEE ON THERAPEUTIC RESEARCH

*The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research.*

*During the year 1935 the committee issued twenty-five new grants.*

A detailed list of these grants together with a list of publications during 1935, and of unexpired grants made before Jan. 1, 1935, is herewith submitted.

The following is a list of the investigations conducted with the assistance of grants made by the Committee on Therapeutic Research, reports of which were published during 1935:

- 1 The Effect of Parathyroid Extract upon the Serum Calcium of Nephrectomized Dogs. Read Ellsworth and Palmer Howard Futcher. *Bulletin of the Johns Hopkins Hospital* 57: 91-98 (Aug.) 1935.
- 2 Further Observations on the Changes in the Electrolytes of the Urine Following the Injection of Parathyroid Extract. Read Ellsworth and William M. Nicholson. *Journal of Clinical Investigation* 14: 823 (Nov.) 1935.
- 3 Vitamin C Concentrates as Preventives Against Black Tongue with Parallel Studies of the Same Concentrates in the Diets of White Rats. L. E. Booher and G. H. Hansmann. *American Journal of Physiology* 114: 429 (Jan.) 1936.
- 4 Fractionation Studies on Provitamin D. Elizabeth M. Koch and F. C. Koch. *Science* 82: 394 (Oct. 25) 1935.
- 5 The Relation of the Oxidation-Reduction Potential of Yeast Cell Suspensions to the Degree of Reduction of Intracellular Cytochrome. J. P. Baumberger, C. C. Fahlen, R. K. Skow and A. Bardwell. *Proceedings of the XV International Physiological Congress* Leningrad and Moscow, U. S. S. R. 1935.
- 6 Presence of Anti-Pernicious Anemia Principle in Normal Human Urine. George E. Wakerlin. *Proceedings of the Society for Experimental Biology and Medicine* 32: 1607 1935.

- 7 Further Evidence for the Presence of a Toxic Factor in Pernicious Anemia, G E Wakerlin and H D Bruner *Science* 82 494 (Nov 22) 1935
- 8 The Presence in Normal Human Urine of a Reticulocyte Stimulating Principle for the Pigeon G E Wakerlin and H D Bruner *Proceedings of the American Physiological Society, American Journal of Physiology* 113 136 (Sept) 1935
- 9 Iodine in Cabbage, Jesse Francis McClendon and Curtis Ethian Holdridge *Biochemical Journal* 29 272, 1935
- 10 Morphine as a Metabolic Stimulant II G Barbour and Janet Andrews *Scientific Proceedings of the American Society for Pharmacology and Experimental Therapeutics Inc Journal of Pharmacology and Experimental Therapeutics* 54 137 (June) 1935
- 11 Excretion of Mercury After Oral Administration of Mercury with Chalk Yellow Mercurous Iodide and Corrosive Mercuric Chloride Torald Sollmann, H N Cole N E Schreiber, H T deWolf and J V Ambler *Archives of Dermatology and Syphilology* 31 15 (Jan) 1935

#### During 1935 the following grants were made

- Grant 254 C W Edmunds professor of materia medica and therapeutics, University of Michigan Medical School \$200 to investigate the action of the drugs in the digitalis group in animals injected with diphtheria toxin
- Grant 255 G H Hansmann professor of pathology Georgetown University School of Medicine and I E Boober Department of Chemistry, Columbia University \$150 to investigate the effectiveness of vitamin G in the cure of black tongue in dogs and if cases can be found of pellagra in the human being
- Grant 256 Vally Menkin Department of Pathology Harvard Medical School \$200 to investigate inflammation and tuberculosis in relation to immunity
- Grant 257 O W Barlow, assistant professor of pharmacology Western Reserve University School of Medicine \$150 to investigate analeptics versus barbiturates
- Grant 258 Claus W Jungblut associate professor of bacteriology Columbia University College of Physicians and Surgeons \$250 to investigate vitamin C versus diphtheria
- Grant 259 O W Barlow assistant professor of pharmacology Western Reserve University School of Medicine, \$100 to investigate the effects of parasympathetic drugs on the intestine
- Grant 260 George D Shafer associate professor of physiology Stanford University School of Medicine \$60 to investigate the effect of sodium citrate on the vagus
- Grant 261 Robert P Walton assistant professor of pharmacology Tulane University of Louisiana School of Medicine \$100 to investigate the absorption of drugs through the oral mucosa
- Grant 262 Victor E Hall assistant professor of physiology Stanford University School of Medicine \$125, to investigate the mechanism of inhibition of the metabolic stimulating action of dimethylphenol by exposure to low environmental temperatures
- Grant 263 H A Shoemaker associate professor of biochemistry and pharmacology, C E Clymer professor of clinical surgery and Henry H Turner University of Oklahoma School of Medicine \$150 to investigate the blood cholesterol and iodine values in thyroid disease and their alteration by treatment
- Grant 264 Detlev W Bronk Johnson professor of biophysics University of Pennsylvania School of Medicine \$200 to investigate the action of various drugs on the autonomic centers
- Grant 265 George E Wakerlin, head of the Department of Physiology and Pharmacology University of Louisville School of Medicine \$200 to investigate hematopoiesis
- Grant 266 I C Koch chairman of the Department of Physiological Chemistry and Pharmacology the University of Chicago \$250 to investigate the antirachitic potency of irradiated sterols other than ergosterol
- Grant 267 Bernard M Jacobson Massachusetts General Hospital \$250 to investigate the therapeutic effects of the purified liver fractions in pernicious anemia tropical sprue and pellagra
- Grant 268 Walter E Hamberger Department of Pharmacology and Toxicology Yale University School of Medicine \$250 to investigate the mechanism of morphine action with special reference to the excitement in cats
- Grant 269 Francis G Blake Sterling professor of medicine and Marion E Howard research assistant in medicine Yale University School of Medicine \$50 to investigate the use of artificial pneumothorax in the treatment of lobar pneumonia
- Grant 270 Elaine P Ralli assistant professor of medicine New York University College of Medicine \$250 to investigate the effect of carotene on the blood vitamin A
- Grant 271 Carl W Walter Department of Surgery Harvard University Medical School \$250 to investigate the glomus body as the site of action of factors causing the complex wound shock
- Grant 272 Ephraim Shorr assistant professor of medicine Cornell University Medical College \$150, to investigate the value of various ovarian preparations
- Grant 273 Marston T Bogert professor of chemistry, Columbia University \$100 to investigate the chemistry and pharmacology of the quinazoline group

Grant 274 John C Krantz Jr professor of pharmacology University of Maryland School of Medicine \$200 to investigate degradation products of dextrose and their possible utilization in diabetes

Grant 275 Roberta Hafkeshing associate professor of physiology, Woman's Medical College of Pennsylvania \$200 to investigate the effects of sodium barbital and other hypnotics

Grant 276 Eugene Stanton Department of Pharmacology Western Reserve University School of Medicine \$150 to investigate the addiction tolerance and abstinence to various narcotics in animals especially rats

Grant 277 Katharine Henderson Department of Pharmacology, Western Reserve University School of Medicine \$300 to investigate the excretion of bismuth

Grant 278 William H Lewis Jr assistant clinical professor of medicine and Arthur C de Graff professor of therapeutics New York University College of Medicine \$150, to investigate the function of the heart in relation to age

The following grants were issued before Jan 1, 1935 In some cases the grant has expired and an unexpired balance remains, or the work is not yet completed or not yet published

Grant 102 C W Greene professor of physiology and pharmacology University of Missouri Department of Physiology \$250 to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia

Grant 119 Nicholas Kopeloff research associate in bacteriology New York State Psychiatric Institute and Hospital \$100 to investigate bacillus acidophilus milk for the prevention and treatment of summer diarrhea in babies

Grant 143 Cleveland J White M D 104 South Michigan Avenue Chicago \$150 to investigate the local general and prophylactic aspects of superficial fungus diseases of the skin

Grant 153 C W Greene professor of physiology and pharmacology University of Missouri Department of Physiology \$300 to investigate the reaction of the coronary system to drugs

Grant 164 E L Jackson associate professor of pharmacology Emory University School of Medicine \$200 to investigate the antagonism between sodium barbital and insulin

Grant 166 Jean Oliver professor of pathology Hoagland Laboratory, Long Island College of Medicine \$200 to investigate experimental nephritis in the frog

Grant 171 Ernest C Dickson professor of Department of Public Health and Preventive Hygiene Stanford University School of Medicine \$250 to investigate therapeutic procedures against coccidioid granuloma

Grant 192 Carl J Wiggers professor of physiology Western Reserve University School of Medicine \$250 to investigate the effect of drugs on the coronary circulation in intact dogs

Grant 194 Sarah A Riedman Columbia University College of Physicians and Surgeons \$200 to investigate the effect of a high fat or ketogenic diet on the susceptibility of animals to convulsions of experimental origin

Grant 200 Walter Bauer Massachusetts General Hospital the Robert W Lovett Memorial Foundation of the Harvard Medical School \$250 to investigate the anatomy and physiology of normal joints with special reference to rheumatoid arthritis

Grant 201 George R Cowgill associate professor of physiologic chemistry Sterling Hall of Medicine Yale University \$250 to investigate vitamin B in relation to morphine addiction

Grant 202 Charles M Gruher professor of pharmacology Jefferson Medical College of Philadelphia \$200 to investigate the effects of drugs on Bell's muscle trigon and fundus of the urinary bladder and of dilaudid on the intestine of unanesthetized dogs

Grant 204 E B Krumpholtz professor of pathology McManes Laboratory of Pathology University of Pennsylvania School of Medicine \$100 to investigate leukocyte attraction

Grant 209 V C Myers professor of biochemistry and F C Bing Department of Biochemistry Western Reserve University School of Medicine \$250 to investigate iron metabolism

Grant 210 C I Reed associate professor of physiology University of Illinois College of Medicine \$200 to investigate the use of viosterol 10 000 X in seasonal hay fever

Grant 212 William C Rose professor of physiologic chemistry University of Illinois \$375 to investigate the isolation of an unknown dietary essential present in proteins

Grant 213 Richard W Whitehead professor of physiology and pharmacology University of Colorado School of Medicine and Hospitals \$200 to investigate the influence of adrenal cortex extract administration on the resistance to bacterial toxins

Grant 214 E A Park professor of pediatrics and J A Pierce Johns Hopkins University School of Medicine \$200 to investigate the reaction of cartilage

Grant 219 Torald Sollmann professor of pharmacology and Harold N Cole associate professor of dermatology and syphilology Western Reserve University School of Medicine \$100 to investigate the epidemic factor in mercurial salivation

Grant 221 John G Reinhold Department of Public Health Philadelphia General Hospital \$250 to investigate the action of aminoacetic acid in progressive muscular dystrophy

Grant 222 Eugene U Still assistant professor of physiology the University of Chicago \$250 to investigate the changes in the metabolism of the pancreas

Grant 223 Clinton H Thienes professor of pharmacology and Lawrence E Detrick Department of Pharmacology University of Southern California School of Medicine \$200 to investigate withdrawal phenomena in morphine addicted animals

Grant 227 Katharine I Henderson Department of Pharmacology Western Reserve University School of Medicine \$100 to investigate the chemical excretion of mercury and bismuth

Grant 228 Henry G Barbour associate professor of pharmacology and toxicology Yale University School of Medicine \$250 to investigate metabolism and water exchange in morphine habituation

Grant 231 William R Amherston professor of physiology, University of Tennessee College of Medicine \$100 to investigate hemoglobin per fusion fluids

Grant 232 George R Cowgill associate professor of physiologic chemistry Yale University School of Medicine \$250 to investigate the heart in vitamin B deficiency

Grant 236 Charles W Greene professor of physiology and pharmacology University of Missouri School of Medicine \$100 to investigate the pharmacology of the so called specific coronary dilator drugs

Grant 237 Louis N Katz director of cardiovascular research Michael Reese Hospital Chicago \$100 to investigate the action of drugs on the coronary circulation

Grant 238 Roy R Kracke professor of pathology Emory University School of Medicine \$250 to investigate the effect of the oxidation products of aminopyrine and related drugs on the leukocyte counts of rabbits

Grant 239 John R Murlin director and professor of physiology University of Rochester School of Medicine \$100 to investigate the absorption of insulin from the alimentary tract

Grant 240 Kenneth W Thompson Peter Bent Brigham Hospital Boston \$250 to investigate the effects of the thyroid stimulating hormone pituitary its relationship to other substances in the possible control of hyperthyroidism

Grant 241 George E Wakerlin associate professor of physiology and pharmacology University of Louisville School of Medicine \$200 to investigate hematopoiesis

Grant 242 Abraham White Department of Physiological Chemistry, Yale University School of Medicine \$100 to investigate the metabolism of the essential amino acids cystine methionine and histidine

Grant 243 Fred C Koch chairman of the Department of Physiological Chemistry and Pharmacology the University of Chicago \$250 to investigate the antirachitic potency of irradiated sterols other than ergosterol

Grant 245 Carl J Wiggers, professor of physiology Western Reserve University School of Medicine \$250 to investigate the usefulness of drugs in coronary thrombosis

Grant 246 Treat B Johnson, Sterling professor of chemistry Yale University \$250 to investigate the pharmacologic action of some pyridine derivatives in relation to their chemical constitution

Grant 247 Arthur W Grace Department of Medicine Cornell University Medical College \$250 to investigate the use of antimonial compounds in the treatment of lymphogranuloma inguinale

Grant 248 Fred C Koch chairman of the department of Physiological Chemistry and Pharmacology the University of Chicago \$250, to investigate the testis hormone

Grant 249 J Percy Baumberger associate professor of physiology, Stanford University \$200 to investigate the occurrence and oxidation reduction potential of pigments in tumor cells

Grant 250 A R McIntyre professor of pharmacology University of Nebraska College of Medicine \$100 to investigate the effects of the digitalis bodies on the metabolism of dextrose by the cardiac musculature

Grant 251 Bernard Fantus professor of therapeutics University of Illinois College of Medicine \$100 to investigate the titration of the antitoxic value of serum of patients who have received tetanus antitoxin

Grant 252 Fred D Weidman professor of dermatologic research University of Pennsylvania School of Medicine \$100 to investigate the causes of human blastomycosis

Grant 253 Katharine I Henderson Department of Pharmacology, Western Reserve University School of Medicine \$300, to investigate the excretion of bismuth

### Report of the Committee on Scientific Research for 1935

During the year, eighty-seven formal applications received consideration and forty-six awards were made The new grants support research in various medical fields In practically all cases the money was turned over to the financial officer of the institution with which the grantee is connected, with the understanding that it would be subject to requisition by the grantee and that an accurate account of the expenditures would be kept From recent reports by grantees it appears that as a rule their work is making satisfactory progress The final or practically final results of work under forty-two grants have been published or are in the course of publication The results of the work under six grants prior to 1935 are under preparation for publication In the case of twenty-five grants prior to 1935 active work is still in progress, but in several cases reports on results have been published In the case of four grants the files have been closed without the publication of any results Refunds totaling \$950.33 were made during the year of unexpended balances from grants

At the end of 1935, 392 grants have been made by the committee since its establishment in 1903 The total amount expended is \$147,936.09 Only two indications of the significance of this support of medical research are mentioned now, the rise to distinction in medical science of grantees whose early efforts at research were aided by the committee, and the

taking in hand by foundations of research projects work on which in the early stages received support from the committee

The committee ventures to recommend that as nearly as possible the same appropriation be made for 1936 as for 1935,

### Financial Statement for 1935

Balance on hand

namely, \$12,550 for grants in aid of medical research and \$1,200 for expenses of the committee

The financial statement for 1935 is presented, also brief accounts of grants pending at the end of 1934 and a list of the grants made in 1935

Respectfully submitted

COMMITTEE ON SCIENTIFIC RESEARCH OF  
THE AMERICAN MEDICAL ASSOCIATION

LUDVIG HEKTOEN, Chicago, Chairman

Term expires, 1936

C C BASS, New Orleans

Term expires, 1937

JOHN J MORTON, Rochester, N Y

Term expires, 1938

N W JONES, Portland, Ore

Term expires, 1939

MARTIN H FISCHER, Cincinnati

Term expires, 1940

### GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH

#### NEW GRANTS—1935

- Grant 347 Edward S West University of Oregon, \$300, hydroxylated fatty acids in tissues
- Grant 348 Phillips Thygeson State University of Iowa, \$400 trachoma and inclusion virus disease of the genito-urinary tract
- Grant 349 Edward H Schwab, University of Texas, \$200 mechanism of cardiac hypertrophy
- Grant 350 Frederic A Gibbs, Harvard Medical School \$100 fiber system in the cat's brain concerned in convulsions
- Grant 351 W O Thompson Rush Medical College \$300 effect of enzymatic digestion on desiccated thyroid
- Grant 352 W J Nungester, Northwestern University \$250 experimental lobar pneumonia
- Grant 353 Frank R Menne University of Oregon, \$500, metabolism of cholesterol in rabbits
- Grant 354 Roy H Turner Tulane University \$450 physiology of peripheral vessels
- Grant 355 Royall M Calder Kent School Kent Conn 150 mechanism of pneumococcal inflammation
- Grant 356 Jay C Davis, University of Minnesota, \$500 coronary flow and lesions of the aortic valves
- Grant 357 John H Foulger University of Cincinnati, \$500 marrow stimulants in the gastric contents of the hog
- Grant 358 John Field, Stanford University, \$200 nitrated phenols and related compounds
- Grant 359 Israel S Kleiner New York Homeopathic Medical College \$200 analysis of various materials for ascorbic (ascorbic) acid
- Grant 360 A M Wright J J Mulholland and T W CoTui New York University \$300 physiology of sympathetomized dogs
- Grant 361 P L Heitmeyer, University of Oregon \$100 experimental uterine ovarian implants
- Grant 362 Lloyd H Ziegler and Arthur Knudson Albany Medical College \$100 activity after recovery from rickets
- Grant 363 Rachel E Hoffstadt University of Washington \$100 protein and carbohydrate fractions of *Staphylococcus aureus*
- Grant 364 Dean A Collins University of Minnesota \$200, hypertension following ligation of renal arteries in dogs
- Grant 365 Ludwig A Emge Stanford University \$500 effect of castration on malignant tumors
- Grant 366 G E Burget University of Oregon \$500 physiology of cardiac portion of stomach
- Grant 367 Robert Gault and A C Ivy American Institute for the Deaf Blind Evinston Ill \$600 mechanical stimulation of the vibratile organs
- Grant 368 Felix Saunders, University of Chicago, \$250 growth factors for bacteria
- Grant 369 Harold Jeghers Boston University, \$150 vitamin A deficiency in certain diseases
- Grant 370 Richard L Crouch University of Missouri \$500, connections of diencephalon
- Grant 371 A Barnett New York University \$300 measurement of impedance angle in thyrotoxicosis
- Grant 372 John L Ulrich Johns Hopkins University, \$450 cerebral functions in the action of antagonistic muscles
- Grant 373 Frank W Allen University of California \$300 correlation of nucleotide content with glycolytic power of red blood cell in pernicious anemia
- Grant 374 Charles B Huggins University of Chicago, \$400 relation of temperature to hematopoiesis
- Grant 375 Heinrich Necheles Michael Reese Hospital Chicago \$100, action of pitressin on gastrointestinal motility
- Grant 376 Herbert F Thurston University of Indiana, \$300, roentgen ray in treatment of gas gangrene
- Grant 377 Frederick A Fender Stanford University \$600 prolonged stimulation of parts of the nervous system
- Grant 378 Wallace M Yater Georgetown University Hospital, Washington D-C histopathologic basis of bundle branch block
- Grant 379 Victor C Myers (Donald E Bowman) Western Reserve University \$650 chemical test for pregnancy
- Grant 380 N W Popoff Highland Hospital Rochester, N Y \$600 arteriovenous anastomosis
- Grant 381 John R Murlin University of Rochester \$600 testis hormone
- Grant 382 L Goodman A J Geiger and L Claiborn, Yale University \$250 antianemic principle
- Grant 383 Harry Sobotka Mount Sinai Hospital, New York, \$300 enzymatic destruction of blood group carbohydrate
- Grant 384 J Louis Weller George Washington University, \$108 action of certain substances on hematopoietic tissue of the chick
- Grant 385 Erwin Brand and G F Cahill New York State Psychiatric Institute and Hospital \$200 cystinuria
- Grant 386 E V McCollum Johns Hopkins University \$150 adaptation of the eyes to subdued light and its relation to vitamin A
- Grant 387 George D Snell Roscoe B Jackson Memorial Laboratory, Bar Harbor Maine \$500 hereditary changes in germ cells from x-rays
- Grant 388 Tracy J Putnam Boston City Hospital Boston \$150 effect of low voltage current on nervous system
- Grant 389 Tracy J Putnam Boston City Hospital Boston, \$150, mechanism of cortical atrophy in dementia paralytica
- Grant 390 Abraham White Yale University \$100 chemistry and metabolism of the sulfur of proteins

Grant 391 Jessie L King Goucher College, \$50, effect of cortical extract on rats

Grant 392 Edward H Schwab University of Texas, \$150 mechanism of cardiac hypertrophy

## STATE OF WORK UNDER PREVIOUS GRANTS

## 1 COMPLETED DURING THE YEAR

Grant 118 1927 \$1 000 to Edward Reynolds and E A Hooton Harvard University mechanism of erect posture Reynolds Edward and Hooton E A Exploratory Study of the Relation of the Pelvis to the Erect Posture in Living Subjects to be published in the *American Journal of Physical Anthropology or in Human Biology*

Grant 133, 1928 I Lowell Dunn University of Nebraska \$715 spectrophotometric analysis of biologic fluids (refund \$53 14) Dunn F Lowell A Cylindrical Rotating Sector Photometer *Rev Scient Instrum* 2 807 1931 Dunn F Lowell and Sudman A T Ultra violet Spectrophotometry of Human Blood Plasma to be published in *Archives of Pathology*

Grant 162 1929 J P Simonds Northwestern University, \$100 action of cinchophen and its derivatives on the liver Churchill T P and Van Wagoner F H Cinchophen Poisoning *Proc Soc Exper Biol & Med* 28 581 1931 Van Wagoner F H and Churchill T P Production of Gastric and Duodenal Ulcers in Experimental Cinchophen Poisoning *J A M A* 99 1859 1932 Churchill T P and Manshardt, D O Experimental Production of Gastric and Duodenal Ulcers in Dogs in Cinchophen Poisoning *Proc Soc Exper Biol & Med* 30 825 1933 Van Wagoner F H and Churchill T P Production of Gastric and Duodenal Ulcers in Experimental Cinchophen Poisoning of Dogs *Arch Path* 14 860 1932

Grant 198 1931 Gilbert Daldorf (Robert L Dickinson) Grasslands Hospital Valhalla N Y \$200 for a study of the human uterus by casts and other ways (refund \$94) The results will be incorporated in a book by Robert L Dickinson on the Human Vaginal and Uterine Cavities

Grant 203 1931 W J Merle Scott University of Rochester \$300 the role of the adrenal cortex in pyogenic infections (refund \$64 22) Scott W J Merle and others The Influence of Adrenal Cortex Extract on the Resistance to Certain Infections and Intoxications *Endocrinology* 17 529 1933

Grant 209 1931 Wilbur A Selle University of Texas \$150 carbohydrate metabolism in its relation to the growth of tumors See grant 243 1932

Grant 233 1932 Detlev W Bronk University of Pennsylvania \$550 nervous regulation of the circulation (refund \$18 48) Bronk D W and Ferguson L K Impulses in Cardiac Sympathetic Nerves, *Proc Soc Exper Biol & Med* 30 339 1932 Bronk D W Ferguson L K and Solandt D Y Inhibition of Cardiac Accelerator Impulses by the Carotid Sinus *ibid* 31 579 1934 Gammon George D and Bronk, D W Pacinian Corpuscles in the Mesentery and Their Relation to the Vascular System *ibid* 31 788 1934 Bronk D W and Stella G The Response to Steady Pressures of Single End Organs in the Isolated Carotid Sinus *Am J Physiol* 110 708 1935 Gammon G D, and Bronk D W The Discharge of Impulses from Pacinian Corpuscles in the Mesentery and Its Relation to Vascular Changes *Am J Physiol* 114 77 1935

HERMAN L KRETSCHMER, Treasurer

## AUDITOR'S REPORT

January 29, 1936

To the Board of Trustees,

American Medical Association, Chicago, Illinois

Dear Sirs

In accordance with your instructions, we have made an examination of the Balance Sheet of the American Medical Association, Chicago, Illinois as at December 31, 1935, and of the Income Account for the year 1935. In connection therewith, we examined or tested accounting records of the Association and other supporting evidence and obtained information and explanations from officers and employees of the Association, we also made a general review of the accounting methods and of the operating and income accounts for the year but we did not make a detailed audit of the transactions. We now submit our report on the examination, together with related statements as enumerated in the index appended hereto.

In our opinion, based on such examination, the accompanying Balance Sheet and relative Income Account fairly present the position of the Association as at December 31, 1935, and the result of its operations for the year ended on that date, subject to the following qualifications and observations:

(1) The inventories of Materials Supplies and Work in Progress in the amount of \$71,530 59 are stated in accordance with affidavits sworn to by responsible officials of the Association and have not been confirmed by us in any way.

(2) In accordance with the established practice of the Association, no provision has been made for (a) accrued interest on bonds, (b) membership dues unpaid (c) accrued salaries and wages, (d) accrued property taxes for the year 1935, and (e) accrued legal fees.

(3) Subscriptions paid in advance represent an estimated amount based on cash received for subscriptions for the year 1936, received in the month of December 1935. This conforms with the method used in prior years.

(4) Advance payments on publications represent an estimated amount of prepaid subscriptions to Hygeia \$124 003 05 plus \$22 858 00 received in advance for January advertising and directory sales and service.

(5) No liability has been set up for construction work on that portion of the new addition to the Association building which had been completed in accordance with the architect's certificate but unpaid for as at December 31 1935, to the extent of \$31 500 00.

Under date of August 15, 1934 the Association property was appraised by the American Appraisal Company. The value of the property as shown by the appraisal was considerably in excess of the book value of the property. It was decided by the Board of Trustees not to place the appraisal value on the books of account. As recommended by the appraisal company the rates

of depreciation now used are  $2\frac{1}{2}\%$  on buildings and 5% on machinery and equipment calculated on the diminishing book values.

We have received a letter from Messrs Loesch, Scofield, Loesch and Burke acting as attorneys for the Association, stating that at December 31, 1935, the only lawsuit pending against the Association was one filed by Charles R Wiley et al on or about the 14th day of September, 1935, in the amount of \$300,000 00 for alleged libel. The attorneys for the Association state in their letter that "basing our opinion upon the experience of the past thirty years we express confidence in defeating this action." We have also received a certificate from an official of the Association stating that at December 31, 1935, there were no contingent liabilities except the lawsuit here referred to.

Fidelity insurance is carried against the undermentioned officers and employees of the Association in the amounts here stated:

Dr Olin West, General Manager	\$10 000 00
Dr Herman L Kretschmer Treasurer	10 000 00
E C Shelly Cashier	10 000 00
E A Hoffman Assistant Cashier	2 000 00
Sundry Employees (eight \$1 000 00 each)	8 000 00
Total Fidelity Insurance	<u>\$40 000 00</u>

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK, MITCHELL & Co

## REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association

The Judicial Council has had but one interim meeting during the last year. This does not mean that the number of problems brought by individuals and organizations is decreasing but that these problems are in most part similar to those already considered by the full council and can be handled through correspondence by the secretary or chairman. In fact, there has been a very large correspondence on ethical subjects.

COOPERATION WITH COUNCIL ON MEDICAL  
EDUCATION AND HOSPITALS

Certain recommendations made in the last annual report of the Judicial Council and approved by the 1935 House of Delegates to the end that closer cooperation between the Judicial Council and the Council on Medical Education and Hospitals be developed have been complied with. The chairman attended a meeting of the Council, explained the need for closer study between the councils, and was assured that the desire of the House of Delegates would receive sympathetic compliance. The Judicial Council believes that the way thus has been opened for classification of and assistance in some of the problems of the general medical profession which come before it for advice, assistance and decision.

An instance illustrative of the need of joint consideration has recently arisen in which a state legislature has passed a law admitting patients to state medical institutions on certificate of osteopaths, which matter is now under consideration. The proposal for treatment of the patients in such state institutions by osteopaths on an equality with such responsibility as heretofore has been assigned only to doctors of medicine may not be many years removed. The problem of maintaining the quality of professional service now given these patients against degradation or dilution of quality of medical care by the mixing of low standard osteopathic practice with scientific practice will then arise, as will also the same problems with respect to the education of medical students in the university and the training of interns in the hospitals connected with it. In those states where such proposals appear to be under consideration, every effort of the doctors of medicine should be made to prevent action so disastrous to the welfare of the people of the state as a lowering of the quality of medical care. It would hardly seem possible that the people of any state through its legislature would by choice lower the quality of medical service available to its wards in its state institutions below that now easily obtainable. It would seem hardly possible that a state would desire to educate its medical students in theories and practices proved unsound by world wide scientific study. It is even less conceivable that any young man desiring a real and scientific education would knowingly choose such a school with its consequent modification of his privilege to enter licensed practice in another state either through reciprocity or by examination. Another deterring factor to the prospective student would at once arise in the question as to the approval of a hospital operated in connection with such a school as a proper institution for intern and resident training.

## PATENTS

The matter of patenting medical remedies and appliances was investigated some five years ago by the Judicial Council to determine the advisability of a change in the present ethical rule. As a result of opinions obtained from all sections of the country from recognized medical leaders and through its own deliberations, no essential change was recommended to the House of Delegates, although current procedures in many instances were considered far from satisfactory. The subject is at present under investigation by a committee representative of national organizations similarly interested. The American Medical Association has been invited to cooperate to the extent that its Judicial Council for mutual enlightenment and benefit discuss the medical point of view with this committee. A satisfactory solution for this aggravating problem may not be evolved, but

it is gratifying to have recognized that medicine has a similar difficult problem as other professions and to be asked to furnish such experience and assistance as may be of benefit to the whole group

#### CHARGES AND TRIALS

Repeatedly the Judicial Council has called attention to the necessity of closely following proper procedure in the conduct of trials based on charges against members of component and constituent organizations and of the necessity of coordinating the governing by-laws of the state association and its component societies. Apparently the many warnings have not reached the ears of the officers and controlling boards of many state and county societies responsible for action. An example of this disregard for legal principles and constitutional procedure involved a case of such prominence that the decision of the Judicial Council was published in full in a recent issue of *THE JOURNAL*. It must be remembered that the Judicial Council is in no position to judge of the facts involved in any local trial, that it has no knowledge of the facts developed at the trial except a written transcript of the trial, which almost invariably is so incomplete and confused as to inspire serious question as to its value, and that it has no opportunity to review the results of cross examination and therefore is very properly barred by the constitution from consideration of the facts and testimony as to facts except as related to law and procedure under which a given trial is conducted. It must also be remembered that orderly procedure and common legal principles are the right of and a protection to innocent and guilty alike. The Judicial Council refrains from taking advantage of technicalities either for or against accused but seeks to judge fairly on the principles underlying them. The Judicial Council recommends that the delegates from state associations bring this portion of its report to the serious attention of the responsible administering officers and boards of the societies they represent.

#### GROUP HOSPITALIZATION

Group hospitalization and individual hospital insurance plans have been rapidly spreading during the last few years as an effort on the part of hospitals to collect full payment for the hospitalization of people of low income groups who in the past have been and in the future will otherwise be unable to pay their hospital costs. This effort has been accentuated by the recent increase in the numbers of such cases combined with a great reduction in hospital income from endowment funds and public contributions. It is an effort at self preservation and secondarily to fix responsibility on a group that during the depression has been rapidly growing among those who have little sense of personal responsibility and rather expect government or charity to care for their needs. Hospital insurance as an economic device now exists almost nationally and is spreading. The American Hospital Association and various state hospital associations are actively promulgating it.

Whether the scheme is or is not financially or economically sound is not the problem of our organization, but it is our business to see that the furnishing of medical service is not included in the sale of insured hospital accommodations. This can be done if a strong stand is taken and maintained by the organized medical profession which must keep a watchful eye to see that medical care is not initially or later included when the usual sales efforts demand increased benefits to purchasers. It is well known that at the present time independently of the hospital insurance movement various hospitals are invading the field of the practice of medicine sometimes at and sometimes against the desire of the members of our profession involved in such instances. It would seem that in this time of extensive changes in hospital economics the point had arrived at which further marriages between hospitals and staff physicians that make the doctor of medicine the servant of the hospital should be stopped and a series of attempts at divorce among marriages that have already taken place should be instituted. Our accepted ethical principles are adequate at the present time and the cooperation of the Council on Medical Education and Hospitals would be of invaluable assistance. It is not an impossible task

but will need a militant local and national ethical spirit behind it and a frowning on those individuals in the profession who on personal grounds do not object to the gradual subjugation of the medical profession in the growth of hospital domination.

#### ASSOCIATION WITH CULTS

There are several general ethical principles underlying cult practice in its relation to medical practice as carried out by doctors of medicine. Primarily the basis for an ethical code is the well being of the people at large, who are dependent on the profession of medicine for their health. The profession of medicine is the custodian of the accumulated knowledge in medicine and should use it for the benefit of humanity. This knowledge, technical in nature and developed by experience, can be interpreted to the body of the people only by persons educated to understand it and trained to apply it. Of all those professing to heal the sick only the doctor of medicine has sufficient education and training to make use of the information already accumulated and keep abreast of that being developed continuously. We grant that even though this is true no one is compelled to choose only from this group in selecting his medical attendants. The individual may elect to receive his medical care from himself, his neighbor, osteopathy, chiropractic, naturopathy or Christian science, but he is not entitled while under the care of such irregulars to demand that the man educated in scientific medicine furnish opinion and advice to one so far deficient in education that he cannot so understand and apply that opinion and advice as to be able to make satisfactory use of it. Such degrading consultation would cheat the patient out of that which he might expect and the subsequent failure of results bring discredit on the science of medicine. If this is true of the occasional individual consultation, how much greater must it be in the case of repeated or continual miscegenation!

The Judicial Council is in receipt of much correspondence attempting to justify if not to advocate consultations between doctors of medicine and chiropractors, osteopaths, Christian scientists and other cultists and irregular practitioners, also appearance before their societies teaching in their schools, and their admittance to hospital practice on a parity with the medical profession. The universal argument for all the procedures mentioned is based on the false premise "to work them gradually into regular medicine." One of our principles of ethics is as follows: "The obligation assumed on entering the profession

demands that the physician use every honorable means to uphold the dignity and honor of his vocation, to exalt its standards and to extend its sphere of usefulness." Such specious argument as mentioned above seems to the Council to lack substance and be unreal. It seems impossible that knowledge gained through years of scientific laboratory work and teaching can be assimilated by those of less preliminary training and use of scientific methods of investigation and practice ever to fit them to enter a profession the dignity and honor of which, the standards and sphere of influence of which, we are obligated to uphold, exalt and extend for the service the profession can render to humanity. We further are of the opinion that it is just as impractical to suggest that the small percentage of cult practitioners will through close relationship with the membership of our profession be raised to our professional standards as it is to expect the few rot-speckled apples in the apple barrel to become whole because of the preponderance of sound ones. We believe in continuous, complete separation between the true and the specious physician. Our traditional responsibility for the dissemination of sound scientific treatment for the people and for protection against the insidious influence of the weaker among our own is ever present. If and when the time comes that government through legislation places the cultist on the same legal plane with us we must strive to maintain the aristocracy of learning and culture. A physical and professional separation as complete as is possible should be established and maintained.

## COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

*To the Members of the House of Delegates of the American Medical Association*

### I RESOLUTIONS OF THE HOUSE OF DELEGATES

1 The House of Delegates at the Cleveland session adopted the following resolution

*Resolved* That it is the opinion of the House of Delegates of the American Medical Association that physicians on the staffs of hospitals approved for intern training by the Council on Medical Education and Hospitals should be limited to members in good standing of their local county medical societies and that the House of Delegates requests the Council on Medical Education and Hospitals to take this under advisement

The Council has brought this resolution to the attention of all hospitals approved for intern training and it is planned to check staff memberships in connection with all the inspections of hospitals engaged in training interns. In this manner the Council will ascertain to what extent hospitals have complied with the foregoing resolution

2 In its report at Atlantic City last year the Judicial Council referred to the improved methods of administering the Principles of Medical Ethics. It was stated that while each member of the American Medical Association, whether in hospitals, in universities, in clinics or in private practice, is at all times subject to the ethics of the profession, the hospital university or clinic as an entity is not and that by concerted action between the Council on Medical Education and Hospitals and the Judicial Council many harmful and obnoxious practices would cease and others, not now presenting any large problem, would be prevented

For the purpose of carrying out the recommendation of the House of Delegates, the secretary of the Council on Medical Education and Hospitals has appeared before the Judicial Council and the chairman of the Judicial Council has met with the Council on Medical Education and Hospitals and it has been agreed that the latter council, in connection with its regular inspections, will secure such additional information regarding certain phases of hospital practice as may be requested by the Judicial Council

3 A considerable number of resolutions have been brought before the House of Delegates requesting the Council to stimulate among the medical schools greater interest and greater activity in the teaching of economics as applied to the practice of medicine. In cooperation with the Bureau of Medical Economics, a very considerable amount of material bearing on this subject has been sent to the library of each recognized medical school and a questionnaire has been formulated to determine the place occupied by economics in the medical curriculum. However, personal conferences with deans and others have indicated that in most schools it is difficult to find a member of the faculty, or any one outside the faculty, who is sufficiently familiar with the problems of medical economics to present to the students a satisfactory discussion of this subject. Merely to add extra hours, labeled economics, to the curriculum and to require students to attend dull or perfunctory lectures would serve no useful purpose and it seems to be evident that teachers will have to be specially trained for this purpose before worthwhile courses in economics will be generally available

### II ACTIVITIES OF THE COUNCIL

4 (a) The survey of medical schools which was undertaken two years ago is, so far as inspections are concerned, nearly completed. Eighty-seven medical schools in the United States and Canada have been visited. The two remaining institutions will be covered before the end of the school year. The Council is now engaged in analyzing and tabulating material that has been obtained, and while there is a great deal of work to be done in the course of preparing a complete report on this survey certain facts are already evident. During the past ten years owing in part to the increasing number of applicants and in part to financial pressure, some schools have increased their enrolment beyond the numbers to which they are prepared to give adequate instruction. While in certain cases the physical plant may be inadequate and in other cases the teaching staff is insufficient, the most generally observed deficiency is a lack

of clinical material or a lack of satisfactory control over the clinical facilities that can be utilized

In the early years of the Council's supervision of medical education, it was categorically stated that no medical school could be properly conducted that did not have a substantial income apart from students' fees and as a result most of the schools developed other sources of support. Recently, as the result of increasing costs and diminishing incomes, schools are now operating on a budget of which the income is derived solely, or almost solely, from students' fees. Some institutions have even gone further and are contributing substantially from their own income to the general upkeep of the university

(b) In connection with the survey, the Council undertook to visit the schools of osteopathy, but the Associated Colleges of Osteopathy promptly refused to allow representatives of the Council to make any inspection of their institutions. If these schools limited themselves to the teaching of osteopathy, such an attitude might be warranted, but since in many states the osteopaths have demanded or have obtained the unrestricted right to practice medicine, it would seem that the public is entitled to know whether their claim to teach medicine is or is not well founded

(c) To aid in the study of the material obtained in our survey of medical schools and in the formulation of conclusions therefrom, the Council has invited the cooperation of five consultants prominent in the field of medical education who, for the sake of convenience, have been designated the "Blue Print Committee," and who meet from time to time with the Council

5 (a) The annual census of hospitals for 1935 was published in THE JOURNAL of March 7. The cordial cooperation offered by the hospitals is indicated by the fact that reports were received from 96 per cent of all hospitals, representing 99 per cent of the entire bed capacity. The list of registered hospitals contains 6,246 names, a decrease of 88 over 1934. The number of beds, however, has increased by 28,249, so that the total is 1,076,350. Admissions during 1935 were 7,709,942, an increase of 562,526 over 1934. The daily average number of patients was 876,689, an increase from the preceding year of 46,591

(b) During 1935, the Council's staff of hospital examiners made the following visits of inspection

<i>Hospitals</i>	
For internship approval	197
For residency approval	31
Tuberculosis sanatoriums	91
Small hospitals for registration	163
Under 25 beds	130
Over 25 beds	33
	<hr/> 482
<i>Technical Schools</i>	
Schools for laboratory technic	65
Schools for physical therapy technicians	7
Schools for occupational therapy technicians	5
	<hr/> 77
Total inspections	559

(c) In the last eight years about 3,000 different hospitals have been visited one or more times by the Council's inspectors. During 1931 and 1932 more than 600 mental hospitals were visited. In 1933, 1934 and 1935 nearly 600 hospitals for the treatment of tuberculosis were examined. In the past four years, at the suggestion of the House of Delegates, our examiners have also visited over 600 small hospitals. These last are a part of a group of more than 2,000 hospitals on the Register which have never been personally visited either by the Council or by any other organization

6 (a) As reported last year, the examination of schools of occupational therapy has been completed, but since the educational standards adopted by the House of Delegates are to be effective not later than Jan 1, 1939, it seemed best to defer the annual classification of schools until that time. In the meanwhile, the St Louis School of Occupational Therapy, the Philadelphia School of Occupational Therapy, Milwaukee Downer College, and the University of Toronto School of Occupational Therapy have already satisfied the requirements. Other schools are in process of meeting them

(b) The visiting of schools for the training of technicians in physical therapy has been completed and an outline of standards for such institutions will be submitted to the House of Delegates for its approval at the current session

(c) The survey of schools for the training of technicians in clinical laboratories is very nearly completed. One hundred and eighty-seven schools have been inspected and fifteen remain. As soon as appropriate standards for these schools can be formulated, they also will be submitted to the House of Delegates for its approval.

7 In accordance with the instructions of the House of Delegates formulated at the Milwaukee session, the Council has during the past year expressed its approval of examining boards in the following specialties: dermatology and syphilology, orthopedic surgery, pediatrics, psychiatry and neurology, and radiology. Physicians who have obtained the certificate of these boards will receive a special designation in the forthcoming edition of the American Medical Directory.

8 *Publications*—(a) The Council has contributed during the past year to special numbers of *THE JOURNAL* as follows:

Educational	Aug 31 1935
Clinical pathology	Oct 26 1935
Tuberculosis	Dec 7 1935
Radiologic	Feb 22 1936
Hospital	March 7 1936
State Board	April 25 1936

(b) A report of the Council's study of hospitals and sanatoriums for the treatment of patients with tuberculosis, prepared by Dr F H Arestad, was published in *THE JOURNAL* and reprints were widely distributed both in this country and abroad. Favorable comment was received from many sources. Copies of this report were sent to the members of the House of Delegates.

(c) The Council has compiled and published a revised edition of the booklet entitled "Approved Colleges of Arts and Sciences and Junior Colleges." This pamphlet, although it contains only information which is also published by the Office of Education in the United States Department of the Interior at Washington, is greatly in demand because the material is so much more conveniently arranged.

(d) As customary, the Council has been responsible for supplying to the Directory Department revised information concerning hospitals, medical schools and examining boards.

(e) The booklet "Laws and Board Rulings Regulating the Practice of Medicine in the United States of America and Abroad," last revised in 1933, has been discontinued in its present form. The abstracting of state laws can perhaps be more efficiently carried out by the Bureau of Legal Medicine, and the records of state medical boards are for the most part so inadequately reported to us that it would not seem to be worth while to publish information which we know to be incomplete and in some cases unreliable.

9 The Thirty-Second Annual Congress on Medical Education, Medical Licensure and Hospitals was held at the Palmer House in Chicago, Feb 17 and 18, 1936. Included in the program were a paper on "The Accrediting of Higher Institutions" by Dr George F Zook, president of the American Council on Education; a symposium on the "Scope and Objectives of the Undergraduate Teaching of Obstetrics," and a group of papers dealing with the social responsibilities of the physician. The attendance at the congress cannot be estimated but there were 320 who registered as delegates. Seventy-three medical schools and twenty-two state licensing boards were officially represented.

### III RECOMMENDATIONS

10 Now that the survey of undergraduate medical schools is nearly complete the Council has voted to undertake a survey of the graduate training of physicians. In this field there is naturally much more variety of aim and method than in undergraduate teaching. Roughly, graduate courses may be regarded as designed either for the training of specialists or for the improvement of practitioners. Under the former heading opportunities may be further subdivided consisting of systematically arranged courses, including especially courses in those fundamental sciences which are prerequisite for satisfactory development in a specialty, and apprenticeships in which the

student obtains actual clinical experience by assuming greater responsibilities in connection with the care of patients in a hospital, a dispensary or a physician's office. The second objective, namely, the improvement of practitioners, is achieved by means of instruction at many different levels ranging all the way from attendance at meetings of the county society or a hospital staff to a prolonged course of study in some graduate or postgraduate institution. This sort of instruction can also conveniently be classified under two main headings: first, those courses of instruction offered by recognized institutions in large centers of population with abundance of clinical material and, second, what may be called extension courses, in which the instruction is carried to the physician in or near his own home by selected teachers operating under the direction of the educational committee of the state society or some similar organization.

11 The work imposed on the Council in connection with the visiting of hospitals for the purpose of appraising the training of interns and residents in connection with the educational requirements of an increasing number of special examining boards, in the visiting of small hospitals as requested by the House of Delegates, and in the supervision of schools for the training of technicians for occupational therapy, physical therapy and laboratory diagnosis, has grown so rapidly in recent years that the present staff of the Council cannot satisfactorily discharge all the responsibilities laid on it. It would seem to be necessary, therefore, to add to our force an additional hospital inspector.

### REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

*To the Members of the House of Delegates of the American Medical Association*

The work of the Council on Scientific Assembly during the past year has proceeded along the usual lines, and all matters that have come within its province have received official attention.

The regular annual Conference of Section Secretaries with the Council on Scientific Assembly was held in Chicago, Dec 16, 1935, and the usual arrangements for the official program of the annual session were made. A Session on Tuberculosis will be held in the Section on Miscellaneous Topics.

A splendid program has been prepared for the General Scientific Meetings to be held on Monday and Tuesday, May 11 and 12. Two distinguished foreign physicians, Lord Horder of London and Dr Amaral of São Paulo, Brazil, will participate in this program as invited guests.

At the Atlantic City session in 1935 a resolution introduced by Dr J Richard Kevin, delegate from New York, proposing that a Committee on Medicolegal Blood Grouping Tests be organized, was referred to this council. A committee has been appointed to study the general subject involved and, in due time, will submit a report to the House of Delegates.

## ETIOLOGY OF AMYLOID DISEASE

The etiologic mechanism in amyloid disease is not yet entirely clear, several theories have been proposed. Among the more important of these, according to Eklund and Reimann,<sup>1</sup> are (a) a general disturbance of protein metabolism, (b) an antigen-antibody union and precipitation, (c) an absorption of protein, (d) a disturbance or abnormality of the reticulo-endothelial system, (e) hyperglobulinemia, and (f) hyperproteinemia and disturbance of the reticulo-endothelial system. The first theory has received experimental support from several sources and relatively recently in the work of Grayzel and his co-workers.<sup>2</sup> Amyloidosis was produced in albino mice by subcutaneous or intramuscular injections of a 5 per cent aqueous suspension of sodium caseinate. Comparative studies indicated that a well balanced, thoroughly adequate diet retarded the production of amyloidosis. The investigators concluded, therefore, that amyloidosis is probably the result of an endogenous protein metabolic disturbance. When the rate of formation of these catabolic products exceeds the ability of the tissues to dispose of them, amyloid appears. The theory of antigen-antibody union has been probably the most popular one in Germany. Thus Letterer,<sup>3</sup> who has extensively reviewed the subject and carried out many experiments, believes that the antigen-antibody precipitation occurs within the organ tissue and that the antigen is a homogeneous fused protein. Stoeber,<sup>4</sup> on the basis of clinical observations, finds the histologic relations between amyloidosis and the condition of the reticulo-endothelial system and stellate Kupffer's cells in the liver especially striking. This relationship suggests, he believes, some as yet unknown abnormality of the reticulo-endothelial system as a factor of etiologic significance.

Eklund and Reimann have continued to favor the hyperglobulinemia theory. They investigated the prob-

lem in rabbits observed over long periods. After the blood protein level had been determined in five rabbits, each animal was given an intramuscular injection of 5 cc of a 10 per cent solution of sodium caseinate three times a week. Injections were continued until shortly before death. Two rabbits were kept as controls in similar cages and were given similar food. The protein content of the plasma was measured weekly during the first four months and then twice a month. The albumin and globulin values of the blood were determined by the method of Medes and the fibrinogen value by the method of Cullen and Van Slyke. Necropsy was performed immediately after death in each case, and sections of tissue were tested with aqueous solution of iodine and double-normal sulfuric acid, congo red and methyl violet. The rabbits were observed until death from amyloidosis occurred. It was not possible to determine when amyloid was first deposited. The changes in the blood protein content observed in each of the rabbits were remarkably uniform. The globulin content in each case rose above the normal level approximately two weeks after the first injection and continued to rise for from four to six weeks thereafter, at which time the amount was from two to four times the normal value. It remained at those high levels during the first four or five months and then declined but remained above normal until death occurred. The albumin content remained constant though slightly below normal for four or five months and then dropped rapidly until half or less of the initial amount remained. The total protein content rose during the second week, reached its highest level in from four to six weeks, and remained high for four months or more.

Each of the five rabbits studied died with signs and symptoms of uremia caused by extensive amyloidosis of the kidneys. Histologically there was almost complete replacement of the glomerular tufts by a homogeneous substance which gave the characteristic amyloid reaction with methyl violet and Mallory's trichrome stain. Within this substance were a few spindle shaped, compressed remnants of nuclei. The capillary spaces were usually obliterated. The stroma between the glomeruli and the persisting tubules, however, failed to react like amyloid substance.

These experiments showed that constant hyperglobulinemia induced by repeated injections of sodium caseinate preceded the development of amyloid disease in each of five rabbits. The authors believe that these observations lend considerable support to the theory that chronic hyperglobulinemia is an important factor in the development of amyloidosis of the secondary type. If the amount is not too great or too persistent, the excess can be disposed of successfully. Furthermore, experimental studies and clinical observations show beyond doubt that the process is reversible. It is misleading, Eklund and Reimann believe, to attempt to correlate the changes in the blood protein level found

in advanced amyloidosis with the etiology of the disease. The conditions are different during the incipient period, and the amount of blood protein, especially the globulin, is above normal. In the late stage, when evidence of renal disease is likely to appear, the total protein content is reduced below the normal level because of the marked diminution in albumin.

Although the evidence regarding the etiology of amyloidosis is still conflicting in many respects, the work reported here strongly suggests that chronic hyperglobulinemia is either an etiologic factor or a corollary of amyloidosis itself.

### DIETS OF FAMILIES WITH LOW INCOMES

The economic depression with its inevitable detrimental effects on the food supply of many families has renewed interest in studies of the diets of groups with low incomes. Recently attention was directed in these columns<sup>1</sup> to a survey in which a relation was shown to exist between the weights of children of the depression-poor families and their diminished income. A statistical survey of the diets of families with low incomes has been reported.<sup>2</sup> The data were collected in the spring of 1933 in nine localities, including Baltimore, Birmingham, Cleveland, Detroit, New York, Pittsburgh, Syracuse, a cotton mill area in South Carolina, and a coal mining district in West Virginia. At least 100 white families living in the poorer neighborhoods but not in the "slum" districts in each locality were questioned regarding the kinds and quantities of food purchased during a period of one week. Sufficient data were thus collected to give a general indication of the relative consumption of the various foods or food groups, such as milk, meats, bread, cereals, vegetables and fruits. The families were then classified according to their incomes, and the average quantities of the various foods and food groups were computed for families in each income class in each locality.

The data collected not only bring out a number of interesting tendencies in food selection but also show the existence of a distinct relation between the character of the diet and the family income. Regional differences in the dietaries also were apparent. In the families living in the six Northern cities there was a direct relation between the calories provided in the dietaries and the income. Members of families with a weekly income of less than two dollars per capita obtained an average of only 2,470 calories a day, expressed as "adult male units," and approximately one fourth of this group received less than 2,200 calories a day per adult male unit. These values are decidedly less than the 3,000 calories recommended by some authorities as an adequate daily allowance for the moderately active adult male. As might be expected,

the caloric content of the diet was particularly inadequate in larger families composed of from five to eight members. As the family income increased there was a steady increase to satisfactory values in the daily caloric content of the diet, families with a weekly income of from three to four dollars per capita receiving an average of 3,180 calories daily. In the Southern communities, however, the decided difference between the caloric value of the diets of the various income groups did not appear. Even in families at the lowest income level, the average caloric value of the diet equaled or exceeded the adequate standard. This apparent inconsistency was attributed to the general use of large quantities of fat meat, cereal foods and syrups in the Southern localities.

One of the most noticeable features of the dietaries in all the communities surveyed was the uniform lack of sufficient amounts of milk, vegetables and fruits, according to current standards, and the consistent overuse of meats and fish, eggs and sugary foods. In the six cities studied, the average supply of milk was one-third less than the minimum suggested requirement and the amounts of fruits and vegetables were no more than just equal to the minimum needs. On the other hand, meat and fish, eggs and sugary foods were used in larger quantities than those recommended for an adequate low cost diet. Such a distorted type of dietary is undoubtedly low in calcium and probably does not contain optimal amounts of certain of the vitamins. A further indication of the inadequacy of the diets of families with low incomes lies in the fact that the incidence of sickness was found to parallel the income of the families investigated.

Surveys of this type call attention to the need for a widespread dissemination of knowledge to the poorer classes regarding a more satisfactory manner of choosing foods in order to insure a more nearly adequate diet at a minimum cost.

### CHOLINE AND FAT METABOLISM

The methods available for the study of processes of intermediary metabolism include a wide variety of experimental procedures and materials. One of the most important of these approaches involves the production of a pathologic condition in the normal organism in an effort to infer from the variations that occur what routes the normal metabolic processes probably follow. Frequently clinical material exists which represents deviations from the normal and thus provides valuable supplementary data for interpretation. As the liver is the chief organ concerned with the metabolism of the three principal types of foodstuffs, experimental or clinical alterations in the liver are usually associated with some aberration of a metabolic process. It has long been of interest, therefore, to study instances of pathologic change occurring in the liver in the patient or produced in the experimental animal.

<sup>2</sup> WicHL Dorothy G. Diets of Low Income Families Survey in 1933. Pub. Health Rep. 51: 77 (Jan. 24) 1936.

One of the most striking changes occurring in the liver is increase in the content of fat. The signs of failure of liver function are peculiarly prominent in depancreatized animals, taken together with the state of the liver at postmortem examination these indicate a profound disturbance in fat metabolism. These results in the depancreatized dog were early attributed to an impaired assimilation of fat and led to efforts to augment the digestive powers of these animals by the addition of raw pancreas to their diet. This form of medication produced striking increases in the length of the survival periods of these dogs. Following the discovery of insulin by Banting and Best, it was demonstrated that the depancreatized dog, receiving insulin but no raw pancreas or pancreatic enzymes, could be kept alive and well for two years. These observations suggested that the beneficial effect of raw pancreas in the diet of depancreatized dogs does not depend on the content of digestive enzymes in this tissue. It therefore became of interest to establish the identity of the factor that is essential to the life of depancreatized dogs. The variations which they evidenced in fat metabolism and the importance attached to the phospholipids in this metabolism led to an attempt to substitute lecithin for raw pancreas in the diet of the depancreatized dog<sup>1</sup>. The beneficial results obtained were striking, the symptoms exhibited by the animals and the results of necropsy suggested an improvement in liver function. Furthermore, it seemed likely that an investigation of the effect of lecithin on the deposition of fat in the livers of normal animals might be of interest. Experiments of this type conducted by Best and his collaborators in Toronto and by Channon and his group in Liverpool have provided interesting information regarding fat metabolism and suggestive possible relationships to the transformations in the body which involve protein<sup>2</sup>.

It is a relatively simple matter to produce abnormally high concentrations of fat in the liver experimentally by feeding either cholesterol-containing or high-fat diets to the experimental animal. Using this technique as a method of approach, the Toronto investigators were able to demonstrate that the administration of lecithin could prevent the ordinarily observed increase in the amount of liver lipids. Furthermore, a study of the component portions of the lecithin molecule yielded the striking observation that the prevention of fat deposition in rats and dogs was due solely to the choline present in the lecithin. In addition, results have been obtained which demonstrate that choline not only is effective in preventing the accumulation of liver fat but may also exert a "curative" action when added to the diet of animals whose livers have previously been made high in lipids by simple experimental manipulation of diet. This unique and interesting

property of choline has been termed by Best the lipotropic action of choline.

The discovery that the choline content of the diet exercises a controlling influence on the amount of fat in the liver has provided the means for many investigations into the subject of fat metabolism. One of the most interesting results obtained from the use of this lipotropic action of choline has been the observation by Best and by Channon that the quantity of protein in the diet has a profound effect on the extent to which the action of choline is manifested. This has led to the demonstration that protein per se has a definite lipotropic action, which differs only superficially from that exhibited by choline. It remains for future investigation to determine whether the ability of the protein in the diet to prevent the accumulation of liver fat is to be attributed to an adhering impurity, either choline or choline-like in nature, or whether this interesting property can be assigned to a constituent of the protein molecule. The development of this chapter of fat metabolism is evidence of sound theoretical reasoning and logical experimental investigation. The subsequent information regarding fat metabolism, and the manifold possible relationships to the transformations of protein in the organism, are awaited with interest.

### SKIN TESTS

With the increasing use of the skin for the detection of various sensitivities<sup>1</sup> it is important to keep in mind that the reactions elicited in the skin give merely a visible record in part at least of the immunologic past history of the patient and per se do not portray a present illness. A correlation between positive tests and the history and observations in the allergic patient is necessary for an accurate diagnosis. The earlier reports of Rackemann and Simon<sup>2</sup> and recently of Grow and Herman<sup>3</sup> of the observations in so-called normal persons are of interest. Grow and Herman find that about 50 per cent of persons without discernible allergic complaint are positive to one or more substances on intracutaneous testing. The question of variations in technique as well as irritability of reagents is a factor of error which they mention. The possible role of fluctuations in nervous, emotional and physiologic activity, as well as the choice of skin area tested have been shown greatly to affect the reactivity to the tests<sup>4</sup>. investigators prefer to read the doubtful reactions (one plus) as positive, others regard the same responses as insignificant. The differences in resulting interpretations frequently leave the management of the patient in a most unsettled state. A few qualified allergists of wide clinical and technical experience make and read skin tests with judicious restraint and thus properly utilize a diagnostic procedure of unquestionable value.<sup>5</sup> However, the indiscriminate use of skin tests for the solution of puzzling clinical problems is apt to lead physician and patient far afield. Present indications are that developments in clinical allergy will lead in two general directions: either many new and heretofore unconsidered substances will be found allergenic or there will be a distinct swing toward nihilism. Evidence of this is seen in the types of research in the field. One seeks to uncover newer or more refined test materials, the other is engaged in studying the fundamental, underlying immunobiologic mechanism. The much discussed and uncertain ground between idiosyncrasy and allergy also is worthy of further investigation. The lack of agreement between workers in allergy is evidence enough that the personal factor in both physician and patient is in each case to be fully evaluated. Whether the skin test is patch, scratch or intracutaneous, the accuracy of our conclusions must rest in the close correlation of symptoms and course with exposure and withdrawal respectively of the substances incriminated by this method of detection.

### ANNUAL GOLF TOURNAMENT AT KANSAS CITY

The American Medical Golfing Association will hold its twenty-second annual tournament at the Mission Hills and the Kansas City Country Clubs in Kansas City on Monday, May 11.

Thirty-six holes of golf will be played in competition for the seventy trophies and prizes in the nine events. Trophies will be awarded for the Association Championship, thirty-six holes gross, the Will Walter Trophy, the Association Handicap Championship, thirty-six holes net, the Detroit Trophy, the Championship Flight First Gross, thirty-six holes, the St. Louis Trophy, the Championship Flight, First Net, thirty-six holes, the President's Trophy, the Eighteen Hole Championship, the Golden State Trophy, the Eighteen Hole Handicap Championship, the Ben Thomas Trophy, the Maturity Event, limited to Fellows over 60 years of age, the Minneapolis Trophy, the Oldguard Championship, limited to competition of past presidents, the Wendell Phillips Trophy, and the Kickers' Handicap, the Wisconsin Trophy. Other events and prizes will be announced at the first tee.

#### MEMBERS IN EVERY STATE OF THE UNION

M. M. Cullom of Nashville, Tenn., is president and W. Albert Cook of Tulsa, Okla., and Walt P. Conaway of Atlantic City, N. J., are vice presidents of the American Medical Golfing Association which was organized in 1915 by Will Walter, Wendell Phillips and Gene Lewis, and now totals 1150 members, representing every state in the Union. The living past presidents include Thomas Hubbard of Toledo, Ohio, Fred Bailey of St. Louis, Edward Martin of Media, Pa., Robert Moss of LaGrange, Texas, Charlton Wallace of New York, Will Walter of Chicago and Charlottesville, Va., James Eaves

of Oakland, Calif., D. Chester Brown of Danbury, Conn., Samuel Childs of Denver, W. D. Shelden of Rochester, Minn., Walter Schaller of San Francisco, Edwin Zabriskie of New York, Frank A. Kelly of Detroit, John Welsh Croskey of Philadelphia, Homer K. Nicoll of Chicago and Charles Lukens of Toledo.

#### KANSAS CITY COMMITTEE

The Kansas City Committee is under the general chairmanship of Clarence Capell, Rialto Building, Kansas City, Mo. He will be assisted by E. R. Deweese, Vice Chairman, and L. G. Allen, J. Wallace Beil, C. D. Cantrell, Logan Clendenning, C. C. Denmie, Hugh A. Gestrung, A. C. Griffith, John S. Knight, T. A. Kyner, A. W. McAlester Jr., Virgil W. McCarty, C. R. McCubbin, C. A. McGuire, C. J. Mullen, Paul J. O'Connell, A. J. Rettenmaier, H. M. Roberts, E. Kip Robinson, C. E. Sanders, J. S. Snider, Albert S. Welch and D. A. Williams.

#### TWO COURSES

To accommodate comfortably the large entry that is anticipated, the Kansas City Committee has arranged play over two very fine courses, which touch corners the Mission Hills Country Club and the Kansas City Country Club. Their club houses are only one mile apart and ample transportation between the two has been arranged. Dinner for all players will be served in the Mission Hills Club House.

#### APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A. M. G. A. Write the executive secretary, Bill Burns, 2020 Olds Tower, Lansing, Mich., for an application blank. Participants in the A. M. G. A. tournament are required to furnish their home club handicap, signed by the secretary. No handicap over 30 is allowed, except in the Kickers' (Blind Bogey). Only active members of the A. M. G. A. may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

The twenty-second tournament of the American Medical Golfing Association promises to be a happy affair. The officers anticipate that some two hundred medical golfers from all parts of the United States will play.

### MEDICAL TRAP SHOOTERS ASSOCIATION

The American Medical Skeet and Trap Shooters Association has been formed by a group of Kansas City physicians and it is hoped that the organization will be permanent. On the afternoon of May 10 there will be a Skeet and Trap Shoot at Elliott Gun Park.

Trap shoot—fifty sixteen yard targets

Class A, 94 per cent

Class B, 89 per cent

Class C, 84 per cent

Skeet shoot—fifty targets

Class A, 21 to 25

Class B, 17 to 21

Class C, 16 or below

A trophy will be given for each class. Our transportation will leave from the Hotel President at 1 o'clock, May 13. Address all correspondence to Dr. A. W. McAlester III, 2003 Bryant Building, Kansas City, Mo., or to Dr. Dar Stoffer, Professional Building, Kansas City, Mo.

Bring your shotguns as well as your golf clubs.

### RADIO BROADCASTS

The American Medical Association broadcasts over WEAT the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of 'Medical Emergencies and How They Are Met'. The title of the program is 'Your Health'. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast 'Ladies and gentlemen your health'. The theme of the program is repeated each

<sup>5</sup> Alexander H. L. Interpretation of the Skin Test Used in Allergic Disorders. *Journal Lancet* 56:131 (March 1) 1936.

week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night, for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

**Red Network**—The stations on the Red network of the National Broadcasting Company are WCAF, WEEL, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOV, WDAF.

**Pacific Network**—The stations on the Pacific network are KGO KPO KFI, KGW KOMO KHQ, KFSD, KTAR.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

April 7 Let Your Doctor Decide R G Leland M D  
April 14 Summer Camps Morris Fishbein M D  
April 21 Health and the School Morris Fishbein M D

#### Undergraduate Education in Obstetrics

DR CHARLES B REED, Chicago. The sentimentalists are maintaining that maternity cases are not getting adequate medical care and that the American mortality and morbidity rate is much higher than in other countries. The charge has not been substantiated. Nevertheless the social theorists and salaried altruists use it freely as an argument for the passage of paternalistic and unconstitutional laws together with a prodigal expenditure of public money. The following statistics, however, from the League of Nations are illuminating.

Mortality and Morbidity 1933

	All Deaths Per 1 000 Population	Infant Deaths Per 1 000 Births	Diphtheria per 100 000 Population	
			Deaths	Cases
Government controlled				
Germany	11.2	76	5.6	114
England and Wales	12.3	63	6.3	117
Scotland		81	7.2	180
No government control				
United States	10.7	59	3.9	39
Illinois	10.5	49	1.7	22

The accusation that maternity cases are not competently managed is a more serious statement which reflects on the teachers in the schools of medicine the curriculums and the character of the teaching. There is some reason to believe that not all colleges offer modern courses of obstetric training. That such a condition does exist is evident from the numerous articles that have appeared in the literature. In 1931 Adair presented a comprehensive study on education in obstetrics. In the same year and as a part of the same White House con-

ference on maternal care, Tindley reported an elaborate scheme for the teaching of undergraduates. So far as can be learned, nothing practical has been done during the intervening years to carry out the valuable suggestions submitted by either man. I propose to suggest a method whereby the quality of undergraduate work can be bettered. This method is a well tested procedure which provides for definite improvement in the care of maternity cases by the general practitioner and facilitates at the same time the growth of specialism. The plan is not new and it can be put in operation anywhere at relatively small expense by a competent faculty. A textbook is essential to success. The books in general use are too large and too verbose. No textbook for the use of students should require more than 500 or 600 pages, if carefully prepared. Several members of the obstetric department at Northwestern University Medical School have made a skeletonized abstract of the modern doctrine in a booklet of about 110,000 words. It avoids futile discussions that are incomprehensible to an undergraduate. This text has been used for years with success. There is no formal lecture, only a quiz. The teacher constantly holds before the students a vision of the high importance of the obstetric art without confusing them with a mass of verbiage and conflicting theories which no one has resolved.

The student is introduced to obstetrics in the last quarter of the second year or whenever the laboratory and basic science courses have terminated. The class should be divided into sections of about forty men and put in charge of a young and enthusiastic member of the department. They learn the textbook thoroughly and recite from it in class. Each section should have at least twenty hours a quarter of this work during each of the four quarters, or eighty hours in all. The student is drilled and redrilled on this fundamental material in a give and take conference.

Late in the junior or early in the senior year the student is assigned to the manikin. He must now visualize the actual mechanics of labor and learn to meet the complications that arise. This degree of skill can be obtained only by familiarity with the instruments employed. The student must feel the instrument in his hands and apply it to the tissues in accordance with its law. It is by practice and only by assiduous practice that he can secure that excellence of judgment, that fine adjustment between the idea and the action which constitutes technic. Practice on the manikin then is, in my opinion, the first and most vital step toward technical efficiency for the student.

Throughout as many quarters as necessary, the class should again be divided into sections of thirty or forty men, who are allotted twelve or more periods of two hours each on the manikin, in which a dead fetus is used. The first hour is spent in listening to a lecture by a senior man in the department, who takes up a given complication of labor, describes the methods of diagnosis, the impending difficulties and the reasons for giving aid together with the indications and conditions that determine the choice of intervention. At the proper moment he illustrates the technic of the operation by slow and careful maneuvers on the manikin and gives the reasons for each act and its difficulties. When the demonstration is finished the lecturer assigns the next topic for study from the manikin textbook. The class is again subdivided into groups of five or six and each group takes its place at a manikin with an experienced instructor from the junior faculty in charge. The student is now required to perform the operation he has just witnessed and repeat it under criticism until every detail of the procedure is thoroughly understood.

In this course the student is trained in the use of forceps for all the appropriate emergencies. The whole hour is spent by the section in practice on each single maneuver. All the malpositions of the head are taken up in turn for study, comparison and differentiation. The management of breech cases comes next. In due course versions are considered and prolapse of the cord and extremities until the entire list has been covered. The student repeats each operation until he can perform it with reasonable dexterity. In every case the student examines the concealed fetus and makes a diagnosis of presentation and position from the distinctive anatomic features, which he recognizes by touch. Then having visualized the problem and decided on the appropriate treatment he is prepared to teach his hands and brain to cooperate. The obstetric course as outlined occu-

pies about 100 hours and, since the hours are spread over a period of two years, it might be advisable to expand the present limitations

Meanwhile, time for the student who elects it is provided in the maternity clinic, where minor technical maneuvers are practiced so that the principles of modern antepartum care may be regularly inculcated. The student is next introduced to actual case work either in the hospital or by domiciliary practice in the outpatient department, under supervision.

The manikin course must be regarded as the most vital part of the obstetric education for the undergraduate, while its stimulating reaction on the older departmental attendants is one of its most gratifying features.

No school should be entitled to a class A rating which does not offer a complete and well thought out course in manikin conferences like the one described. However eminent a lecturer may be, he cannot convey to students a clear understanding of obstetric problems without more patience and determination than he is apt to give unless he uses the manikin. The processes, which are wholly mechanical, are too complex for easy visualization by an uninitiated mind. The problem in undergraduate instruction is to grind in the fundamentals and let the knowledge broaden and increase as the mind grows with experience.

I studied the catalogues of fifty-seven of our best schools and sent out a questionnaire. Among these fifty-seven schools, only thirteen devoted ten or more hours to manikin instruction. Among twenty-nine others, thirteen did not mention the subject in their catalogues, while in sixteen the manikin was used only for casual illustration by the lecturer. The students had no access to it. From fifteen colleges no information was obtainable. The only deduction from this survey is that manikin teaching is not provided in about 75 per cent of our schools. This omission is not altogether creditable to an obstetric department. Until the condition is corrected, medical men will not be able successfully to confute the imputations that our maternity cases do not get adequate care.

### **The Public Health Aspect of the Teaching of Obstetrics in Undergraduate Medical Schools**

DR ROBERT H. RILEY, Baltimore. This article will be published in full in *THE JOURNAL*.

### **Undergraduate Obstetric Education**

DR FRED L. ADAIR, Chicago. This article will be published in full in *THE JOURNAL*.

### **DISCUSSION ON SCOPE AND OBJECTIVES OF THE UNDERGRADUATE TEACHING OF OBSTETRICS**

DR PAUL TITUS, Pittsburgh. The obstetric education of medical students and young doctors seems to be steadily improving even though it can stand infinitely more improvement. The question frequently propounded is "When should the teaching of obstetrics to medical students be begun?" It cannot begin too early. Anatomy and embryology, physiology and physiologic chemistry, bacteriology and pathology would be intensified in their interest to students if the multitude of ways in which they apply to obstetrics could be pointed out in the preclinical years. I should like to ask how often an obstetrician is requested to discuss the female bony pelvis before a first year class in anatomy or has an opportunity to describe to first or second year students the effects of bacterial contamination during labor and delivery. Abnormalities demonstrated on the manikin properly supplement classroom and textbook instruction in the last two years, but a reasonable amount of clinical work with frequent clinical conferences should dominate the fourth year. Obstetrics and gynecology should not be divorced in teaching. The two are inseparable, and there is a trend toward a combination of these chairs in schools of medicine. The intern year should be universally compulsory before a license is given to practice medicine. The American Board of Obstetrics and Gynecology, of which I have the honor to be secretary, has just completed a survey of graduate training facilities in our specialty in the hospitals of this country. I regret to say that the planned opportunities for clinical training toward outright specialization are much greater than those for the general hospital practitioner. The unfounded charge made by social workers and popular writers that the maternal mor-

tal and morbidity rates are much higher in America than elsewhere in the world is grossly inaccurate for the reason that vital statistics of the various countries of the world have no common denominator by which they can be compared. If we in the United States include in our maternal mortality rates, as some states do, women who die from illegal abortions we are being more honest, statistically, than certain countries which classify as a puerperal death only women dying after a "live-birth," and live-births as including only babies that live long enough to be baptized. The medical ability of our doctors will be useless if women remain so indifferent that they fail to seek antepartum care. Rother's fifteen-state survey showed that 54 per cent of the women dying from childbirth causes in a given period had had little or no antepartum medical care. There are three hopeful facts in what is admittedly a high death rate from maternal causes. The first is that constant propaganda is being carried on to teach women and physicians the value of antepartum care. The second is that puerperal death rates are slowly but steadily declining in this country, according to statistics of the Metropolitan Life Insurance Company. The third evidence of progress is that symposiums such as this are being presented to audiences deeply concerned with improvement in education in obstetrics.

DR W. S. LEATHERS, Nashville, Tenn. The maternal mortality rate of this country has not appreciably declined during the past decade. Each year more than 2,000,000 mothers in the United States reach the parturition period, and approximately 13,000 of them die during childbirth. Furthermore, during the past year about 70,000 infants died during the first month of life, which is 58.2 per cent of the total mortality of this age group. Probably 75 per cent of this mortality could be prevented. The neonatal mortality is greatly influenced by the kind of medical service afforded during delivery. It is estimated that 40 per cent of the maternal mortality is due to puerperal infections and 27 per cent to toxemias. Other causes are accidents of pregnancy and labor, a lack of skill, inadequate antepartum care, a lack of aseptic obstetric practice, interference with normal labor, and unnecessary cesarean sections. Midwifery constitutes a serious problem, particularly in the Southern states and among the foreign element in the larger cities. In a few Southern states about 50 per cent of the cases of confinement are attended by midwives who are ignorant and untrained for such service. These facts emphasize the necessity of devoting more attention to the teaching of obstetrics to undergraduate medical students. Approximately 44 per cent of the people of the United States live in rural areas, where mothers must depend largely on the general practitioner for obstetric service. The scarcity of practitioners of medicine in many rural areas and the distances that have to be traveled to interview the doctor frequently preclude the possibility of obtaining adequate antepartum and postpartum supervision. Even though adequate instruction in obstetrics is provided for undergraduate medical students, the problems of rural practice make it difficult to provide antepartum and postpartum care without the cooperation of public health agencies. Indeed, this is fundamental. One of the most encouraging trends at this time is the establishment of full time county and district health services. In 1930 there were 3,075 counties and of this number there were 2,675 in states which now have one or more full time county, township or district health departments. This development is of the greatest importance in attaining the objectives in obstetric practice. At Vanderbilt the fourth year class is divided into groups which visit in rotation two full time county health departments that are well organized and in which antepartum and postpartum care are provided efficiently. All students spend two afternoons discussing this and other phases of the local health program. If some such procedure should be followed in the instruction of undergraduate medical students it would serve as a means of enlisting the continued support and active cooperation of practitioners in the future in this service. Obviously, adequate consideration should be given to obstetrics in the curriculum for undergraduate students. The basic requirement should be an improvement in the quality of instruction in the outpatient service and in the ward supplemented by attendance at twelve or more home deliveries if possible, under the supervision of a member of the resident

staff Each student should also be given an understanding of the public health aspects of obstetric practice and the relation that should be maintained by the practitioner and the local health service. There is also need for more appreciation on the part of the public and in general the medical profession concerning the requirements in modern obstetric service.

DR E. D. PLASS, Iowa City Antepartum care has been in operation more or less extensively in this country for approximately a quarter of a century. During that time there has at least been no reduction in the maternal mortality. Those who are hypercritical might assume from this that antepartum care cannot save lives. Those of us who are concerned with obstetrics believe that that is a false assumption and look for an explanation in the increase in operative obstetrics. Apparently, the harm of the latter balances the good of the former. It is curious that the public thinks of the recent graduate in medicine as being perfectly competent to handle any obstetric case. The individual who would not allow a recent graduate to remove her gallbladder or appendix is content to subject herself to obstetric operation by a recently graduated physician. If we face those propositions together, it seems that we arrive at two alternatives. One, that we should prepare our medical graduates to handle obstetric emergencies and to do obstetric operations after the fashion of the more experienced, or that we should educate the lay public to the dangers of obstetric operations and to the necessity of especially trained operators. If we cannot provide what has been described here as adequate obstetric training for our students, we certainly cannot provide this more advanced training which would give a proficiency in operative technic. I resent the idea that these problems of maternal mortality go back directly to the teachers of obstetrics. I believe that, before we condemn those teachers too severely, we should think that the woman herself has a considerable burden to bear, and until we educate the public to these dangers we shall not have an improvement in our maternal mortality statistics.

DR GEORGE W. KOSMAK, New York I have little to add except possibly to controvert the idea that I assumed that a greater practical experience of the medical student with patients, such as I have suggested in this increased outdoor service, would fit the young graduate to perform obstetric operations. I think it would have the exactly opposite effect. I think that a student who is made responsible, under supervision, of course, for the adequate delivery in an obstetric case becomes more duly impressed with the fact that labor is a physiologic process and that his main duty is to watch it and to see that it is carried out properly rather than to think of short cuts for delivery. It is these short cuts for delivery that have done so much to increase our maternal mortality rates. I tried to show that, as a basis for a change in our teaching, we would have to take into consideration the increased operative incidence in obstetric deliveries which seem so prevalent in this country. Does that increase in operative deliveries mean that our women are less able by their natural forces to bring to an end this process of labor? I hardly think that is an explanation. I think that our women are just as competent as the women of other countries to do this. They are no worse off than these women with whom they are compared, so that something else must enter into the picture, and I think that something else is this great desire on the part of improperly and insufficiently trained medical men to devise short cuts in obstetric deliveries which are not really called for.

FEBRUARY 17—EVENING

## THE FEDERATION OF STATE MEDICAL BOARDS

### The Responsibility of a University in Medical Training

EUGENE A. GILMORE, LL.B., Iowa City The standardization activities of the American Medical Association, the Federation of State Medical Boards and the Association of American Medical Schools have been of invaluable service in the elimination of unfit and incompetent schools and practitioners. Moreover, the public has traveled along with the standardization program and has supported it, notwithstand-

ing the vigorous dissent of certain minorities and despite misgivings that the program was tending to place needed medical care beyond the reach of the masses. Standardization cannot run too far ahead of prevailing sentiment. Current discussion affords evidence of growing resentment against high medical costs and of the beginnings of various movements to establish socialized, syndicated or collective devices to circumvent difficult access to what the medical profession has taught the people to believe is very desirable. The solution does not lie in abandoning or lowering the standards or withdrawing the emphasis but rather in an educational program designed to create in the people an appreciation of the value of the standards and their importance to the public welfare and, more important, in impressing on the profession itself a keener sense of its social obligations.

Without disparaging but, on the contrary, praising those who have worked in the interest of higher standards for medical education and practice for the public good, one must recognize that the guild motive of monopoly has been in the minds of some of the most ardent advocates of high standards. Evidence of this is especially apparent in connection with the technic used for the selected lists of medical specialists in various fields. There is much talk about an excess of physicians. It is urged that a formula must be found which will tell how many doctors are needed for a certain number of people, and that only that number should be educated and licensed. Rather, more and better doctors are needed, better in every sense better in technical knowledge, skill and training, better in personality and character, better in general education, better in appreciation of the social implications of the healing arts and their relation to other instrumentalities of general welfare. What constitutes an excess? Excess is purely a relative term. It varies with the environment, with the economic condition of the people, with the scope and intensity of their appreciations, and with their educational and cultural development. Who would have predicted twenty-five years ago that the people of the United States would have the capacity to use 30,000,000 automobiles or 15,000,000 radios? The cosmetic industry and the beauty parlor came from an aroused interest in personal appearance. This was one activity that flourished and expanded even in the darkest days of the depression. Formal education is another one. Theoretically there is a point of saturation for everything. Too much reliance, however, should not be placed on artificial formulas to determine the scope of the demand and what constitutes an excess. In our laudable pursuit of standards, we are prone to accept such artificial formulas, to resort to numbers and formal tests as a basis of selection, to assume that the community's capacity to consume has been reached and to assume that mere quantity necessarily results in deterioration of quality. What all professions need is to become more conscious and confident of their own potentialities of growth and development. They need to get a better historical perspective of organized society and a more adequate appreciation of the potentialities of a people growing in intelligence and wealth to use skilled services. For the time being and for the prevailing type of doctor, we may have too many as society is now organized and as scientific development now stands. But science, art and civilization are not static.

The development of this historical perspective is the chief responsibility of the university in medical training. Its realization will come through a broader education, both in the pre-medical and in the medical periods. It must likewise train men adequately for the practice of the art of medicine. Here it may let the vocational objective predominate, but the pursuit of a vocational end can be made in a liberal atmosphere. There is a third function which the university should assume, and that is the orientation of the prospective physician in a large and cultural general education which will enable him to appreciate the possibilities of his own profession and also to appreciate the social implications and responsibilities of his profession. Such orientation can be made by the liberalization of the present premedical and medical courses. Its more perfect attainment will come, however, when the technical medical course rests on the general education represented in the curriculum of a college course in liberal arts. If the university is to be charged with a responsibility for medical training, it might insist that the present medical curriculum proceeds too much on the

assumption that professional education is a mere process of acquiring information. The result of this assumption is a tendency to load programs of professional education with a maximum of informational topics which it is felt a physician should know. This attempt to teach all things to all men represents an unwarranted faith in mere information. It overlooks what should be continually kept in mind in any program of sound education, namely, that truly educated men can be trusted to learn some things for themselves.

### The Art of Medicine

DR IRVIN D. METZGER, Pittsburgh. The former preceptor plan gave the prospective medical student an insight into the workings of the art in medicine. His ambitions to enter the profession then were either frustrated and his efforts diverted into more suitable lines of endeavor, or they were enhanced so as to place before the student an envisaged challenge which pictured a needy patient at every stage of his subsequent scientific development. Now students are shunted from the secondary to the professional schools and on to the verge of graduation before they sense the meaning of medical practice. Attempts are made through required internship, as a fifth year of medical training, to make amends for the dearth of clinical experience. In the internship an opportunity is given to develop a sense of responsibility not offered by the medical school. If the intern is held responsible for the condition of patients in the absence of his chief, he gets a feeling of what it means to have the lives of helpless people hanging trustfully on his judgment and conscience. He thus may grow in the grace and charm and wisdom of a real physician. Unfortunately, many medical minds are so surfeited with hard medical facts that they can scarcely be induced to mellow into that plastic mentality which can evaluate the clinical condition of the patient, which can elicit the subtle factors which underlie functional aberrations and which can sanely apply their medical knowledge to the needs of their patients.

Medical artistry cannot be acquired through abstract rationalization, such as is followed in the acquisition of medical knowledge. It must be attained by experience. An encyclopedic knowledge of medicine not only fails in itself to encompass the needs of adequate practice but may positively hinder the prospective doctor in attaining even a mediocre measure of success. Medical knowledge, when logically acquired, is indispensable to professional perfection but it must be only the stairway on which professional striving mounts into artistic professional realism.

The art of medicine requires the physician to enter into the lives of his patients. Not only must he know what are the variable general trends in human nature but he must be able to individualize the ones most dominant in the life of each. An adequate history of a patient involves not only the physical abnormalities of the past but also salient factors in the mobilized mental status that now exists. The ability to comprehend the social and environmental factors that enthrall the patient may open the gateway which leads to the restitution of a healthful morale. The artist in medicine discerns the purports of life. He who sees in his patient just another case that is suffering from a conventional disease fails as a physician even though he may cure. This businesslike attitude of many recent physicians savors strongly of exploitation. Its recognition by social workers and politicians urges them to call for medical regulation by the state. If practitioners of medicine made it less a business and more a mission of mercy, their plea for a maintenance of the sacred relations between physician and patient would not seem so much of a mockery. We have scarcely touched this most vital factor in the development of a practical physician. Perfection in fact finding and in scientific technique has been our aim so that we have lost sight of the real goal—the production of a creative personality with a stalwart character. The time is not far distant when administrators of the medical laws will be less concerned about the scientific knowledge which candidates possess but much more about the mental, the moral and the social adaptability to the profession which the candidates for licensure possess.

All recognized medical schools furnish ample scientific training to assure reasonable service to the sick. Why should we spend more or less futile efforts in further assuring ourselves

in this matter? Relatively few schools, even in these days of better pedagogic instruction in medical schools, fathom intimately the deeper factors of personality in the individual student. Many medical schools fail to take note even of the physical condition of its students, what may we expect in respect to the more subtle mental trends? It seems to me that any licensure granted to a candidate should be conditional. If a license when granted should be limited to a period of some five years, after which a renewal for permanence would be required by the state board, a means of control would be available. Exploiters could be eliminated before they became socially grounded. Quasiethical nuisances could be curbed before they brought reproach on the entire profession. Amateur specialists could be halted before they demoralized the faith of the community in the integrity of the profession. Bunglers in practice would be offered an opportunity to seek a more suitable vocation. The problems facing us may be variable but in essence are similar. Wholesome policies for one state are helpful in every other. Cooperation with medical organizations renders a mutual service, and must always be encouraged by our boards. Let us demand of our candidates not less factual knowledge in the science of medicine but more effectively trained minds in its application. Then we may hopefully expect the evolution of many masters in clinical medicine.

(To be continued)

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Personal**—Mr. William A. Byrne has resigned as special agent of the state board of medical examiners, after several years' service, effective February 12.—Dr. Wesley W. Beckett, Los Angeles, has retired as medical director of the Pacific Mutual Life Insurance Company, after thirty years' service, he has been succeeded by Dr. Linford H. Lee, assistant medical director. Dr. Beckett becomes medical director emeritus.

**Japanese Night at Medical Club**—The International Medical Club sponsored a Japanese night at its meeting, March 27, in Los Angeles. Guests of honor were Dr. Harlin Shoemaker, president of the Los Angeles County Medical Association, Hon. Tomokaya Hori, consul for the Japanese government, Dr. Daishiro Kuroiwa, president of the Japanese Medical Association, and Mr. Congoro Nakamura, president of the Japanese Chamber of Commerce.

**Society News**—Dr. Arthur L. Bloomfield, San Francisco, discussed "Clinical Aspects of Streptococcus Infection" before the Palo Alto Medical Society, February 24.—Dr. Archibald A. Alexander, Oakland, discussed lead poisoning before the Contra Costa County Medical Society, February 11.—At a recent meeting of the Monterey County Medical Society in Pacific Grove, Dr. Edwin F. Kehr, Carmel, spoke on "Hypoglycemia and Hyperinsulinism."—Speakers before the San Bernardino County Medical Society recently in San Bernardino included Dr. Walter F. Pritchard, San Bernardino, on "Urologic Complications of Pregnancy."—Dr. Platt W. Covington, Salt Lake City, addressed the San Joaquin County Medical Society in Stockton, February 6, on "Research on Influenza" and Dr. Emmett Rixford, San Francisco, "Industrial Accidents."

### DISTRICT OF COLUMBIA

**Rockefeller Grant to Howard University**—Howard University School of Medicine, Washington, has received a grant of \$100,000 from the Rockefeller Foundation, to be used over a period of five years toward the developments of the departments of medicine and surgery.

**University News**—Dr. Charles O. McCormick, Indianapolis, gave a lecture at Georgetown University School of Medicine, February 28, on "Analgesia in Labor." A course in medical social economics has been added to the curriculum of the senior year. Lectures on the various aspects of the subject are given by different authorities. Present lecturers are

Drs Arthur C Christie, Oscar B Hunter, Henry C Macatee, George C Ruhland, J Russell Verbrycke Jr, Wallace M Yater and Mr Ross Garrett

**Medical Bills in Congress**—H R 12035, introduced (by request) by Representative Norton, New Jersey, proposes to provide for the treatment and care of persons addicted to the use of intoxicating liquors. The bill provides for an appropriation of \$200,000 to erect buildings to house and treat addicts and provides that any person who has been convicted on charges of drunkenness or intoxication three or more times within the year immediately prior to the last conviction shall be deemed to be addicted to the use of intoxicating liquor. H R 12036, introduced by Representative Scott, California, proposes to provide for the establishment, in the District of Columbia, of a system of social insurance, by the enactment of a "Workers' Social Insurance Act."

### FLORIDA

**Society News**—Dr James S McLester, Birmingham, Ala., President, American Medical Association, addressed the Hillsborough County Medical Society in Tampa, February 24. A joint meeting of the Dade and Broward County Medical societies was addressed in Miami Beach, March 16, by Drs William V P Garretson on "The Psyche in Relation to Physical Symptoms," John F Erdmann "Tumors of the Uterus," Joseph F McCarthy, "The Prostate and Adnexa Considered from the Standpoint of Obstruction as a Potential Focus of Infection and of Other Constitutional Manifestations," Andrew A Eggston, "Newer Application of Clinical Pathology to Diagnosis," and Joseph D Kelly, "Relation of Otolaryngology to Allergy." All are of New York.

### ILLINOIS

**Society News**—Dr John S Coulter, Chicago, addressed the DuPage County Medical Society, February 19, in Elmhurst on "Physical Therapy in the Treatment of Chronic Arthritis." Speakers before the Hancock County Medical Society, March 2, were Drs Harold Swanberg and Walter M Whitaker, Quincy, on "Modern Treatment of Cancer of the Uterus" and clinical use of electrocardiography respectively. At a meeting of the Perry County Medical Society in Duquoin, March 5, Dr Eugene Lee Shrader, St Louis, discussed "Coronary Disease" and Dr James L Mudd, St Louis, "Surgical Treatment of Lung Suppuration."

### Chicago

**Personal**—Dr Antome Lacassagne, associate director of the Curie Institute of Paris, lectured at Michael Reese Hospital, March 10, on "Modern Conception of Radiation in the Treatment of Cancer." Dr Jacob Frank observed his eightieth birthday, March 16.

**Society News**—At a meeting of the Chicago Gynecological Society, March 20, Dr Harold H Hill, Oak Park, Ill., among others, discussed "The Value of the Sturmdorff Cone for Biopsy Material in the Detection of Early Carcinoma of the Cervix Uteri." The Chicago Society of Internal Medicine was addressed, March 23, among others, by Dr Harry A Singer on "Pyrexia Due to Gastric Carcinoma." Speakers before the Chicago Society of Industrial Medicine and Surgery, March 25, were, among others, Drs James H Hutton on "Endocrinology in Industrial Medicine," Philip H Kreuscher, "Surgery of Arthritis" and Rosco G Leland, "Changes Confronting Modern Medicine."

**Slayers of Dr Peacock Confess**—Four young Chicago robbers have confessed to the murder of Dr Silber C Peacock, a specialist in children's diseases, January 2. Dr Peacock had been lured from his home on a fake telephone call, presumably to attend a sick child. The robbers awaited his arrival at the address given and during the encounter he was beaten shot and robbed of \$20. The members of this gang are youths from 17 to 19 years of age, living on the northwest side. They have been identified also by the following four physicians as the hoodlums who recently robbed them of the amounts indicated after the receipt of a fake telephone call to attend a patient: Dr Joseph F Konopa of \$11, Dr Raymond L Abraham, \$57, Dr Bernard C Kolter, \$19, and Dr Lars A Garness, \$6. Dr John P O'Connell was also held up by the gang on the street March 20. It is reported that about forty other victims of robberies have filed complaints against these youths. Shortly after Dr Peacock's death, the Chicago Medical Society appointed a committee to assist the police in handling this situation and this committee continued to be of service until

the murderers were captured. The society not only offered a reward for the apprehension of the murderers of Dr Peacock but arranged with the police department to have a detective accompany, on request, any member of the society who was called out at night to attend a patient.

### IOWA

**Lecture Series**—The Jefferson County Medical Society and the speakers' bureau of the Iowa State Medical Society began a series of lectures at Fairfield, March 12, with Dr Nathaniel G Alcock, presenting the first lecture, on "Malignancies of the Urinary Tract, with Special Reference to Treatment." Other lecturers in the series are:

Dr Willis M Fowler, March 19, Diagnosis and Treatment of Nephritis  
Dr Horace M Korns, March 26, Medical Treatment of Nontuberculous Diseases of the Lungs  
Dr Howard L Beye, April 2, Surgical Treatment of Diseases of the Lungs and Pleura  
Dr Philip C Jeans, April 9, Specific Treatment of Infectious Diseases  
Dr Frank R Peterson, April 16, Minor Surgery of Today

All the speakers are members of the faculty of the state University of Iowa College of Medicine, Iowa City.

**Society News**—The Clinton County Medical Society was addressed in Clinton, April 2, by Drs Everett D Plass and Ewen M MacEwen, both of Iowa City, on "The Obstetric Pelvis" and "Some Phases of Medical Education" respectively. Dr Henry C Hesselstine, Chicago, addressed the Dubuque County Medical Society, February 11, on "Recent Advances in the Treatment of Vaginal Discharges." At a meeting of the Jasper County Medical Society in Newton, February 4, Dr Kenneth L Johnston, Oskaloosa, discussed goiter. The Johnson County Medical Society was addressed in Iowa City, February 5, by Dr Edward A Schumann, Philadelphia, on "Obstetric Deaths." Dr Richard H Jaffe, Chicago, addressed the Scott County Medical Society in Davenport, February 4, on "Classification of Splenomegalies."

### KANSAS

**New Buildings at Medical School**—A clinic building, a four story children's ward, a research laboratory and a warehouse will be erected this year at the University of Kansas School of Medicine. The children's ward is being financed by \$48,000 of federal funds and an anonymous donation of \$60,000. The warehouse will be financed with \$10,000 appropriated by the state legislature and \$8,000 from federal funds. The Hixon Laboratory for Medical Research, which will replace the temporary structure now in use, will cost \$60,000, of which \$35,000 is an anonymous gift and \$25,000 federal funds. The clinic will be constructed with \$55,000 accumulated for this purpose by Bell Memorial Hospital over a period of years and with \$45,000 from federal funds, according to *Modern Hospital*.

### KENTUCKY

**Personal**—Dr John B Floyd, Richmond, has been appointed to a position on the staff of the state board of health to succeed the late Dr Jethra Hancock.

**Society News**—At a meeting of the Third District Medical Society in Bowling Green, February 19, the following speakers discussed various phases of treatment of gonorrhea: Drs John C Burch and Jefferson C Pennington, Nashville, George M Wells and Lawrence O Toomey, Bowling Green. The Southwestern Kentucky Medical Association held its quarterly meeting in Marion, February 25, with Drs Joseph Gant Gaither, Hopkinsville, and Edward B Willingham, Paducah, as speakers on handling of automobile injuries and pneumoconiosis, respectively. Dr Roy Glenn Spurling, Louisville, addressed the Harlan County Medical Society, Harlan, February 15, on "Meningococcic Meningitis." About 100 cases have recently been reported in the county.

### LOUISIANA

**Personal**—Dr Ford S Williams, Oak Grove, director of the health department of West Carroll Parish, has been appointed to a similar position in St Mary Parish, succeeding Dr Walter W Poinboeuf, Franklin, resigned.

**Society News**—Dr Nathaniel G Alcock, Iowa City, addressed the New Orleans Urological Society, recently, on "Treatment of Bladder Neck Obstruction." The Fourth District Medical Society was addressed, March 3, by Drs Vilray P Blair, St Louis, on "Indications and Technique for Skin Grafting," and Jason P Sanders Caspiana, "Present Day Trends in Treatment of Malaria." Dr Ruffin A Paine, Shreveport, discussed endocrinology before the Shreveport

Medical Society recently — The Bi-Parish Medical Society was addressed recently by Drs Andros S Hamilton and Stanford Chaille Jamison, New Orleans, on "Common Foot Diseases" and "Acute Vascular Failure in Common Medical Diseases"

**Decoration Bestowed on Dr Matas**—Dr Rudolph Matas, honorary chief of the surgical service at Touro Infirmary, was presented with a decoration and the title of commander of the National Cuban Order of Carlos Finlay and a diploma of honorary fellowship in the Academy of Medicine of Havana, March 9, at the annual meeting of the Southeastern Surgical Congress in New Orleans. The presentation was made by Dr Charles Edward J Finlay, Havana, Cuba, son of Dr Carlos Finlay. Last year Dr Matas resigned as chief senior surgeon at Touro Infirmary, a position he had held since 1905. He had been professor of surgery at Tulane University School of Medicine of Louisiana from 1895 to 1927. He was vice president of the American Medical Association in 1921 and again in 1932.

#### MAINE

**Cosmetic Law Upheld by Federal District Court**—A law was enacted in Maine in 1933 prohibiting the sale of cosmetics not registered with the bureau of health. Subsequently the Federal District Court, District of Maine, enjoined the enforcement of the act, presumably on the ground that it contravened provisions in the constitutions of Maine and of the United States. A cosmetic bill was then drafted, which its proponents believed obviated the constitutional defects in the 1933 law. This bill was presented to the 1935 legislature, which passed it and on the governor's approval it became a law (C 109, Public Laws, 1935). The new law prohibits, after Jan 1, 1936, the sale of cosmetic preparations not registered with the department of health and welfare and authorizes the department to refuse to register or to prohibit the sale of cosmetic preparations "which in its judgment contain injurious substances in such amounts as to be poisonous, injurious or detrimental to the person." An attempt was made to have the same federal district court enjoin also the enforcement of the new law, but the court, February 19, refused to do so holding that no evidence had been presented to it to show in what way, if any, the new law offended provisions in the state or federal constitution. The state may now enforce the provisions of the cosmetic law, which, it is believed, if properly enforced, will eliminate from the Maine market cosmetic preparations that may be detrimental to health.

#### MARYLAND

**Personal**—Dr Silas W Weltmer, who has been acting superintendent of the Spring Grove State Hospital, Catonsville, since the resignation of Dr Robert E Garrett in November 1935, has been named superintendent—Dr Ira A Darling, superintendent of the Warren State Hospital, Warren, Pa, has been appointed superintendent of the Springfield State Hospital, Sykesville.

**Industrial Training Course**—A special training course for inspectors of industrial hygiene and safety, the first of its kind to be conducted on an interstate basis, was held in Baltimore for ten days beginning February 10 according to Baltimore *Health News*. The instruction, which was supplemented by a series of inspection visits made possible by the cooperation of local industrial plants, was sponsored by the division of labor standards of the U S Department of Labor, and the lecture and conference sessions were held at the Johns Hopkins School of Hygiene and Public Health. Miss Frances Perkins secretary of labor, attended the closing exercises, February 20 and presented certificates to the twenty-five members of the course who hold official positions in West Virginia, North Carolina, Tennessee, Maryland and in the Baltimore health department.

#### MASSACHUSETTS

**State Farm Quarantined for Meningitis**—The Bridgewater State Farm Bridgewater, was under quarantine March 10 when an outbreak of meningitis was reported. This was the second ban placed on the institution in recent weeks on account of the disease, newspapers reported.

**Society News**—Dr Bernard Appel Lynn, addressed the Essex South District Medical Society in Lynn, March 4 on syphilis—At a meeting of the New England Heart Association in Boston March 23 speakers included Drs Harold M Teel on Cardiac Asthma and Acute Pulmonary Edema as a complication of Nonconvulsive Toxemia of Pregnancy and Arthur T Hertig Angiogenesis in the Early Human Placenta.

**Prize for Essay**—The Massachusetts Medical Society is offering a prize of \$50 for the best written and most comprehensive case report submitted by an intern holding a rotating internship in any Massachusetts hospital approved by the American Medical Association for intern training during 1935-1936. The report is to be typewritten and when completed is to be sealed, unsigned, in a plain envelop, which in turn is to be placed, together with a separate slip bearing the name and address of the contestant, in a larger envelop. It should be mailed to the Massachusetts Medical Society, Committee on Medical Education and Medical Diplomas, 8 The Fenway, Boston, before May 1.

#### MICHIGAN

**State Society Adopts Five Year Program**—At a meeting, January 15, the council of the Michigan State Medical Society approved a five year plan to coordinate and develop the activities of the society. Under the plan, graduate education will be stimulated, the need for proper selection of officers will be emphasized, medical information bureaus will be established in all county societies and information on socialized medicine will be disseminated. Special attention will be given to legislation as it affects the medical profession, and plans for the postpayment rather than prepayment for illness will be developed, according to a statement of the objectives in the *Journal of the Michigan State Medical Society*.

**Foundation Offers Graduate Course**—The W K Kellogg Foundation is offering a two weeks' graduate course in medicine at Washington University School of Medicine, St Louis, beginning April 13, for physicians in Calhoun, Barry, Branch, Eaton, Allegan, Hillsdale and Van Buren counties and Battle Creek, which areas are included in the community health project sponsored by the foundation. The course will be under the direction of Dr Williams McKim Marriott, dean and professor of pediatrics, at the medical school, and it will be adapted to the needs of the general practitioner. Work will begin each morning at 8 30 except on Monday, April 13, when the first meeting of the class will be at 10 a m at the St Louis Children's Hospital, and will continue until 5 p m, with one hour intermission for luncheon. Evening meetings are planned for at least twice a week, starting with dinner followed by round table discussions of subjects in which the physicians are particularly interested. There will be a farewell banquet at the Kings-Way Hotel, Friday evening, April 24. At least 100 physicians are expected to attend the course, the foundation caring for all expenses.

#### MINNESOTA

**Society News**—The Hennepin County Medical Society was addressed, March 25, by Drs Lawrence R Boies and Henry E Michelson on "Tumors of the Nose and Throat" and "Cancer of the Skin" respectively. Dr Fred L Adair, Chicago, will address the society, April 6, on "Placenta Praevia."

**A Country Doctor Honored**—A plaque was presented to Dr Charles L Scofield, Benson, at a testimonial dinner, March 9, given by the Benson Chamber of Commerce, in recognition of his fifty years as a country doctor and forty-six years as "Benson's beloved citizen." Dr Scofield graduated from the University of Iowa College of Medicine in 1886. He was one of the charter members of the Minnesota Association for the Study and Prevention of Tuberculosis, and has served as a member and an officer of the Sanatorium Advisory Commission and the State Sanitary Conference. He was president of the state board of health in 1922. He has served as mayor and a member of the school board of Benson and as a councilor of his district society. Speakers at the dinner included Drs Albert J Chesley, executive secretary of the state board of health, Edward A Meyerding executive secretary of the Minnesota Public Health Association, and William W Will, Bertha, president of the state medical association.

#### MISSOURI

**State Medical Meeting at Columbia**—The Missouri State Medical Association will hold its annual meeting at the Hotel Tiger, Columbia, April 13-15, under the presidency of Dr Edwin Lee Miller, Kansas City, with the Boone County Medical Society acting as host. Monday evening there will be a dinner meeting of the maternal welfare committee, at which Dr Joseph L Baer, associate clinical professor of obstetrics and gynecology, Rush Medical College Chicago, will speak on "Critique of Submitted Maternal Death Reports." Reports of maternal deaths during 1936 will be presented at this meeting. Dr Baer will also address the general meeting Tuesday on

"Operative Obstetrics," and Dr Owen Wangenstein, professor of surgery, University of Minnesota Medical School, Minneapolis, will be the guest speaker Wednesday afternoon on "The Acute Abdomen." Frederick A Middlebush, Columbia, president of the University of Missouri, will speak and the following physicians, among others, will present papers

Sam E Roberts, Kansas City Impaired Hearing Classification and Management

Carlie B Souter Smith Springfield Management of Squint

William M James St Louis Diagnosis and Treatment of Ocular Complications in Syphilis

William Byron Black Kansas City, Rational Treatment of Chronic Sinus Diseases

Jacob Kulowski St Joseph Complications of Pyogenic Osteomyelitis and Their Treatment

John R Green Independence Etiology of Mesenteric Thrombosis

E Lee Dorsett St Louis Prolapse of the Uterus Operative Treatment with Special Reference to the Manchester Operation

Bransford Lewis St Louis, The Loose Kidney Problem and the General Profession

Elmer E Sexton St Louis Problems of the Female Urethra

Jacob G Probst St Louis Serious Complications and Sequelae Resulting from the Injection Therapy of Varicose Veins

John H Ogilvie Kansas City Methods of Examination of Low Back Pain

Sinclair Luton St Louis, The Clinical Use of Digitalis Its Variables

Willard Bartlett Jr St Louis, A Ten Year Mortality Study in Toxic Goiter

Harvey P Doughnau Kansas City Pernicious Anemia

Edward P Heller, Kansas City Management of Injuries to the Spine and Pelvis

Charles E Bell, Ira H Lockwood and Frederick C Narr, Kansas City Tumors of Superior Mediastinum

John H Hershey St Louis A New Method of Nerve Stimulation

Caryl R Ferris Kansas City Modern Trend of the Treatment of Staphylococcus Infection

William M Kinney, Joplin Pathology of Silicosis and Silicotuberculosis

Hyman I Spector St Louis, When Therapeutic Pneumothorax for Tuberculosis Should be Instituted and When It Should be Discontinued

Robert J Crossen, St Louis Endocrine Treatment in Gynecology

Joseph W Larimore, St Louis The Ileocecal Segment

Louis Rasseur St Louis Common Duct Gallstones

## NEW HAMPSHIRE

**Personal**—Dr Ralph E Miller, assistant professor of pathology, Dartmouth Medical School, Hanover, has been promoted to be associate professor and appointed assistant dean of the school. Dr Miller is on leave for the current semester studying in Berlin.

## NEW YORK

**Personal**—Dr George W Corner, professor of anatomy, University of Rochester School of Medicine, has been named Thomas Vicary lecturer for 1936 of the Royal College of Surgeons. The lecture will be given in December on a subject in the history of anatomy or surgery. Dr Corner will also give a series of lectures on physiology of the ovarian hormones under the auspices of the University of London and Guy's Hospital Medical School.—Dr Louis V Waldron has been appointed health officer of Yonkers to succeed the late Dr William S Coons.—Dr George Hoyt Whipple, Rochester, was recently elected a member of the board of scientific directors of the Rockefeller Institute for Medical Research, New York.

**Society News**—Dr Joseph L Baer, Chicago, addressed the Buffalo Academy of Medicine, February 19, on "Prolapse of the Uterus."—Dr Jesse G M Bullowa, New York, addressed the Suffolk County Medical Society at its quarterly meeting in January on pneumonia.—A program on pneumonia was presented at the meeting of the Medical Society of Albany County, February 26, speakers were Drs Otto A Faust, John J Clemmer Jr and Lemuel Whittington Gorham.—Dr Thurman B Givan, Brooklyn, addressed the Medical Society of the County of Nassau, February 25, on the "Diagnosis and Treatment of Congenital Syphilis."—Dr Evarts A Graham St Louis, addressed the Rochester Academy of Medicine, February 6, on "Congenital Cystic Disease of the Lung in Relation to Pulmonary Suppuration."

**Bills Introduced**—S 1771 and A 2130 propose to make it the duty of every attending or consulting physician, nurse, parent or guardian having charge of any minor under six years of age who is totally deaf or whose hearing is impaired "to report the facts to the health officer of the appropriate city, town or village. It is then to be the duty of the health officer to investigate and to have an otologist examine the child and to provide such medical or surgical care and treatment as is needed, if the parents are unable to provide it. S 1790, to amend those provisions of the civil practice act which authorize a court to require when relevant any party to an action and the child of any such party to submit to blood grouping tests and to make the results of these tests admissible in evidence,

proposes that the results of the tests be received in evidence only where definite exclusion is established. S 1791, to amend those provisions of the domestic relations law which authorize the court before whom any paternity proceeding is pending to require the defendant, the child and the mother to submit to blood grouping tests and to make the results of such tests admissible in evidence, proposes to make the results of such tests admissible in evidence only in cases in which definite exclusion is established.

## New York City

**Patients in City Hospitals**—A total of 243,801 inpatients were admitted to hospitals of the city system during 1935 according to the annual report of the commissioner of hospitals. Dr Sigismund S Goldwater. These patients obtained a total of 6,544,472 days of care, an average of 25.1 days per patient. The average daily total of bed patients was 17,930, the report showed. The mortality rate was 6.9 per cent.

**Personal**—Dr George Gray Ward, New York, was a guest speaker at the tenth British Congress of Obstetricians and Gynecologists at Belfast, Ireland, April 1-3. Dr Ward's subject was "Reconstructive Pelvic Surgery for Genital Prolapse."—Drs Anthony Brasser, Max Einhorn and Samuel Weiss have been elected honorary members of the Belgian Gastro-Enterologic Society.—Henry C Sherman, Ph D, professor of chemistry, Columbia University, received the bronze plaque awarded annually by the Alumni Association of the Graduate Schools of Columbia University for "outstanding contributions to the human race." Dr Sherman was honored for his work in nutrition. Louis I Dublin, Ph D, vital statistician, received a scroll of honor at the same time. The awards were presented at a dinner March 17.

**Society News**—At a joint meeting of the New York Heart Association with the section of medicine of the New York Academy of Medicine, March 17, speakers were Drs Lucy D Porter Sutton on "Management of Rheumatic Heart Disease" and Irvine H Page, "Observations on the Mechanism and Treatment of Hypertension."—Drs Harrison S Martland and Raphael Pomeranz, Newark, N J, addressed the New York Roentgen Society, March 16, on "Etiology of Silicosis and Its Medicolegal Considerations" and "Roentgen Findings in Silicosis" respectively.—Drs George Edgar Burford and James Seymour Edlin addressed the American Society of Anesthetists at the New York Academy of Medicine, March 18, on "Continuous Flow Administration of Cyclopropane" and "Common Pulmonary Complications Following Abdominal Operations" respectively.—Drs Richard Kovacs and William Bierman addressed the Bronx County Medical Society, March 18, on "Physiotherapy in Relation to Traumatic Surgery" and "Fever Therapy by Physical Means" respectively.—A symposium on complications of gallbladder surgery was presented at a meeting of the New York Surgical Society, March 11, by Drs Charles Gordon Heyd, Ralph Colp, Leon Ginzburg and Ellsworth Eliot Jr.

## NORTH CAROLINA

**Surgical Meeting**—The North Carolina Academy of Surgery held a one-day conference in Charlotte, March 7. Clinics were held at various hospitals in the morning and a program of addresses was presented in the afternoon at the Hotel Charlotte. Speakers were Drs Fred W Rankin, Lexington, Ky, Dean D Lewis, Baltimore, Joseph E J King, New York, Alfred A Strauss, Chicago, and Edgar I Fincher Jr, Atlanta.

## OHIO

**Personal**—Dr Sidney M McCurdy, Youngstown has been appointed director of the medical division of the Ohio State Industrial Commission, succeeding Dr Hugh H Dorr, Columbus. Dr Roy J Secrest, Columbus, a member of the division's staff for eight years, has been made assistant director.

**Hospital News**—Dr Howard P Doub, Detroit, was the guest speaker at the third clinical institute of the year at the DeEtte Harrison Detweiler Memorial Hospital, Wauseon, February 13. Dr Doub conducted a clinic and spoke on "Diseases and Injuries of the Back and Kidneys." Dr Earl H Baxter, Columbus, conducted the institute, March 26, on "Modern Trends and Advances in Pediatrics."

**Society News**—Dr John M T Finney, Baltimore, addressed the Summit County Medical Society, Akron, March 3 on "Pitfalls to Be Avoided in Surgical Diagnosis."—Dr Walter M Simpson, Dayton, addressed the Cleveland Academy of Medicine, March 20 giving "A Clinical Appraisal of Artificial Fever Therapy."—Dr Charles W Mayo Rochester Minn, addressed the Van Wert County Medical Society, Van Wert,

March 3, on "Comparative Physiology of the Intestinal Tract"—Dr William J Egan, Milwaukee, addressed the Cincinnati Academy of Medicine, March 3, on "Clinical Experience with Ultra Short Wave Therapy"—Dr George M Curtis, Columbus, addressed the Columbus Academy of Medicine, February 10, on "Splenectomy in Treatment of Blood Diseases"

### OKLAHOMA

**State Medical Meeting at Enid**—The forty-fourth annual meeting of the Oklahoma State Medical Association will be held in Enid, April 6-8, under the presidency of Dr George R Osborn, Tulsa. The general scientific meetings of the state association will be Tuesday and Wednesday mornings, with section meetings in the afternoons. Guest speakers will include

Dr William E Sauer St Louis Cancer of the Larynx Things Every OALR Man Should Know Diseases of the Paranasal Sinuses  
Dr Alfred I Folsom Dallas Texas Pylitis in Children Pylitis in Infants Practical Considerations in Treatment of Complications in Gonorrhea  
Dr Arthur E Hertler Halstead Kan Goiter Hernia  
Dr Albert N B Lemoine Kansas City Mo Fever Therapy in Ocular Manifestations of Syphilis  
Dr Ira H Lockwood Kansas City Mo The Use of X Rays in the Diagnosis of Breast Tumors  
Mr G A Criswell Oklahoma City Compensation Insurance  
Dr Robert U Patterson dean University of Oklahoma School of Medicine Some Important Contributions to Medical Science by Military Surgeons

The annual golf tournament will be held Monday afternoon, April 6, at the Meridian Country Club and the Oklahoma Pediatric Society and the Woman's Auxiliary will hold their meetings that day

### PENNSYLVANIA

**Committee on Social Problems**—At a meeting of the board of trustees of the Medical Society of the State of Pennsylvania, February 4, the chairman, Dr Edgar S Buyers, Norristown, appointed a committee of five members of the board to be known as the committee on social aspects of sickness service. This committee is to confer between regular meetings of the board with representatives of the standing committees of the state society or others engaged in the study of the social aspects of sickness service as they may involve plans proposed by county societies for benefit of the indigent, those on emergency relief, those seeking to pay on a budget system and those seeking to provide in advance for the so-called catastrophic illnesses. Dr Augustus S Kech, Altoona, is chairman of the new committee and members are Drs David W Thomas, Lock Haven, George C Yeager, Philadelphia, Robert L Anderson, Pittsburgh, and Laurrie D Sargent, Washington. Members ex officio are Drs Alexander H Colwell, Pittsburgh, president of the state society, Maxwell J Lick, Erie, president-elect, Walter F Donaldson, Pittsburgh, secretary, and Dr Buyers, chairman of the board of trustees. Consultant members are Drs William H Mayer, Pittsburgh, Francis F Borzell, Philadelphia, George L Laverty, Harrisburg, and Chauncey L Palmer, Pittsburgh

#### Philadelphia

**Dr Landis Receives Phillips Medal**—Dr Eugene Markley Landis, assistant professor of medicine, University of Pennsylvania School of Medicine, received the Phillips Memorial Medal of the American College of Physicians at the annual session of the college in Detroit, March 4, in recognition of work in the field of capillary physiology and disturbances of the peripheral circulation. Dr Landis, who is 35 years old, was graduated from the University of Pennsylvania School of Medicine in 1926. In 1929 he received a Guggenheim fellowship to study reactions affecting minute blood vessels with Sir Thomas Lewis in London.

**Auxiliary Sponsors Health Institute**—The Woman's Auxiliary of the Philadelphia County Medical Society will conduct its sixth annual health institute at the society's building, April 14. Among speakers will be

Dr Edward J G Beardsley What Life Teaches the Doctor  
Dr Harriet I Hartley Child Health  
Dr Martin E Rehfuess Diet After Forty  
Dr Joseph C Doane Hearts and the Family Budget  
Dr Louis H Clerf How to Hold Aids to Health  
Dr George E Pfahler Cancer—Increasing Hope for the Patient  
Dr Samuel B Scholz Jr Periodic Health Examination

Mrs W Burrill Odenatt, president of the auxiliary to the Medical Society of the State of Pennsylvania will speak on "The Auxiliary and Its Purpose" and Drs Clifford B Lull, adviser to the auxiliary, and George C Yeager, president of the county society, will bring greetings.

**Society News**—Dr David L Edsall, formerly dean of Harvard Medical School Boston, addressed the section on public health, preventive and industrial medicine, College of Physicians

of Philadelphia, on "The Teaching of the Practice of Preventive Medicine." The occasion was the annual "Student's Night"—Speakers before the Philadelphia Academy of Surgery, March 2, were Drs Bruce L Fleming, on "Inguinal Hernioplasty by Fascial Transplant", Frederick A Bothe and Joseph T Beardwood Jr, "Evaluation of Abdominal Symptoms in the Diabetic," and Virgil H Moon, "An Experimental Analysis of the Symptomatology and Mechanism of Death Following Intestinal Obstruction"—A symposium on "Intracranial Complications of Otorhinc Origin" was presented before the Philadelphia Laryngological Society, March 3, by Drs Oscar V Batson, Benjamin H Shuster and Francis C Grant

### RHODE ISLAND

**Bills Introduced**—S 233, to amend the law regulating the practice of hairdressing and cosmetic therapy, proposes, among other things, to permit such licensees "to remove superfluous hair from the body of any person." H 952, to amend the medical practice act, proposes to provide for the licensing of persons desiring to practice electrolysis by the chief of the division of examiners in the department of public health. Electrolysis the bill proposes to define as "the removal of superfluous hair and the decomposition of such hair by the use of an electric needle or needles." The bill sets out no educational qualifications whatsoever to be exacted of such applicants other than to require applicants to "present satisfactory credentials and submit to an examination" by a competent person appointed by the director of public health. S 289, to amend the laws relating to the practice of osteopathy, proposes that a certificate to practice osteopathy shall confer on the holder thereof "the same rights and privileges and the same duties and obligations as a certificate to practice medicine, except the practice of major surgery, provided, however, that any holder of a certificate to practice osteopathy, who can satisfy the board of examiners that he has completed one year postgraduate internship in a hospital approved by said board, may be granted a license to practice any branch of surgery." The bill further proposes that "all persons receiving the degree of Doctor of Osteopathy and Doctor of Medicine shall be accorded the same rights and privileges under government regulations." H 953 proposes to require any person harboring, or any hospital, maternity home or other institution treating, a woman on whom an illegal abortion has been attempted to report the facts within forty-eight hours after knowledge of the case to the director of the department of public health.

### TEXAS

**Society News**—Drs Marvin D Bell and Elliott M Mendenhall, Dallas, addressed the Grayson County Medical Society, Sherman, recently, on "Melanomas" and "Artificial Pneumothorax Treatment in Pulmonary Tuberculosis" respectively.—Drs John R Nicholson and Otto J Potthast, San Antonio, among others, addressed a joint meeting of the Hays-Blanco, Guadalupe, Caldwell and Gonzales county medical societies in Luling, recently, on "Cystitis as a Symptom" and "Use of Coley's Serum" respectively.—Dr James C White, Boston, presented a paper on "Surgical Measures in the Treatment of Angina Pectoris" before the Harris County Medical Society, Houston, recently.—Dr Prather T Kilman, Malakoff, discussed rabies at a meeting of the Henderson County Medical Society, Athens, February 3.—Speakers at the meeting of the Dallas County Medical Society, April 9, will be Drs Robert L Moore, on "Prevention and Treatment of Measles," Penn Riddle, "Injection Treatment of Hernia," and Julius McIver, "The Cystogram as a Diagnostic Aid in Placenta Praevia"—Dr Ximie R Hyde, Fort Worth, was elected president of the Texas Radiological Society at a recent meeting in Galveston.

### VIRGINIA

**Health at Richmond**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended March 21, indicate that the highest mortality rate (238) appeared for Richmond and that the rate for the group of cities as a whole was 138. The mortality rate for the corresponding week of 1935 for Richmond and for the group of cities was 159. The annual rate for the eighty-six cities for the twelve weeks of 1936 was 137, compared with 128 for the corresponding period of 1935. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area outside the city limits or that it has a large Negro population may tend to increase the death rate.

## WASHINGTON

**New State Secretary**—Dr Vernon W Spickard, Seattle, has been elected secretary-treasurer of the Washington State Medical Association to succeed the late Dr Curtis H Thomson, Seattle. Dr Harrison Garner Wright, Seattle, was made assistant secretary-treasurer. The new address of the state association will be 518 Cobb Building, Seattle.

## WISCONSIN

**Federal Funds to Aid Health Program**—Wisconsin's share of federal funds for health work available under the social security act, about \$139,000, will be used to set up a health organization to demonstrate the value of public health administration on a county basis, according to newspaper reports. The state will be divided into nine districts, each manned by a physician, sanitary engineer, public health nurse and clerk and, in addition, three county units will be established for demonstration purposes. The state programs for control of tuberculosis, gonorrhea and venereal diseases will be augmented. The program was outlined at a meeting in Madison, February 27, attended by an advisory committee representing the State Medical Society of Wisconsin. Members of the committee are Drs Albert H Lahmann and Abraham B Schwartz, Milwaukee; Guy W Carlson, Appleton; Marshall O Boudry, Fond du Lac, and Joseph F Smith, Wausau, Mr J George Crownhart, Madison secretary of the state society, and G B Larson, assistant secretary.

## ALASKA

**Dawson Quarantined for Scarlet Fever**—Dawson was placed under quarantine, March 18, with public gatherings banned, after several persons were stricken with scarlet fever on returning from a carnival at Fairbanks. Schools, churches and theaters were closed, the *New York Times* reported.

## GENERAL

**Death Rate Maintains Same Level**—The provisional death rate for eighty-six cities reporting to the U S Department of Commerce in 1935 was 11.4 per thousand of population, according to figures recently released. Although the total number of deaths was 424,969 in 1935 as compared with 426,990 in 1934, the rate is identical with that of 1934. Cities with the lowest death rates were Yonkers, N Y, Detroit and Flint, Mich., Somerville, Mass., and Akron, Ohio, while the highest rates were in Nashville, Tenn., Washington, D C, New Orleans, La., and Memphis, Tenn.

**Meeting of Anatomists**—The American Association of Anatomists will hold its fifty-second session at Duke University School of Medicine, Durham, N C, April 9-11, under the presidency of Dr Warren H Lewis, Baltimore. More than 150 papers will be read. Included on the program are symposiums on "The Structure of the Hypophysis," "Lymphocytes, Macrophages and Fibroblasts," "Ovulation," "Premedical Education for Anatomy," "Hormones and Development," "Pulmonary Alveolar Epithelium," "Functions and Structure of the Frontal Lobe" and "Effects of the Ovum on Maternal Tissue."

**A Swindler with Tuberculosis**—A man giving the name Robert Crossland has recently been reported as giving to several physicians in Indiana checks which were later returned marked "No account." An Elkhart physician reported to the police that the man came to his office for an examination, giving a history of tuberculosis. At the conclusion of the examination Crossland gave the physician a check for \$12 on the South East National Bank of Chicago. The man claimed that he had been a patient at the Veterans' Administration Facility at Hines, Ill. and was to be transferred to the facility at Oteen, N C. According to the report the man was about 40 years old, 5 feet 7 inches tall and weighed 128 pounds. He gave a history consistent with pulmonary tuberculosis since 1921. Physical examination showed involvement of the left side of the chest, with coarse rales and dullness to percussion. A roentgenogram showed an area of abnormal density about 5 by 8 cm in the lower part of the left side of the chest. The left costophrenic angle was obliterated and the left diaphragmatic excursion markedly limited.

**News of Epidemics**—An epidemic of measles in Dallas, Texas, had affected more than 200 school children with two deaths within two weeks, Dallas newspapers reported March 8. Twenty-one cases of German measles at Lehigh University, Bethlehem, Pa., led to a ban on public gatherings between February 27 and March 11. Classes were not suspended. Fifty-eight families in Westover, Pa., a town of about 800,

were quarantined because of measles, it was reported March 5. The New York City health department reported 1,489 cases of measles during the week ended February 29, an increase of 809 over the number for the corresponding week of 1935. More than forty children were reported to be ill of chickenpox at Oaks, Pa., a small community in Montgomery County. About 140 students at the University of Missouri, Columbia, were reported ill of influenza February 25, there was one death. Influenza was reported to be widely prevalent in upstate New York, March 13, seven schools were closed and it was estimated that about 2,000 children were ill. In Glens Falls, 800 residents were reported to have the disease.

**Medical Bills in Congress**—*Changes in Status* H J Res 538 has been reported to the House, providing for the participation by the United States in the ninth International Congress of Military Medicine and Pharmacy in Rumania, 1937, and proposes to request the President of the United States to invite the congress to hold its tenth meeting in the United States in 1939. H R 3629 has passed the House and Senate, authorizing the acquisition of additional land for the use of the Walter Reed General Hospital. *Bills Introduced* S 4342, introduced by Senator Copeland, New York, proposes to create a Division of Stream Pollution in the Bureau of the Public Health Service. H R 12003, introduced by Representative Hildebrandt, South Dakota, proposes to authorize an appropriation of \$350,000 to erect a veterans' hospital in South Dakota for the diagnosis, care and treatment of general medical and surgical disabilities. H R 11985 and H R 12005, introduced by Representative Ramsay, West Virginia, propose to prevent the manufacture, sale or transportation of adulterated or misbranded or poisonous liquors. H R 12028, introduced by Representative Kennedy, Maryland, proposes to provide hospitalization for certain employees in the Bureau of Navigation and Steamboat Inspection of the Department of Commerce and for licensed local pilots of the United States. H R 12034, introduced by Representative Lemke, North Dakota, proposes to authorize an appropriation of \$180,000 to construct an addition to the veterans' facility at Fargo, North Dakota, for the care and treatment of general medical and surgical disabilities. H R 12059, introduced by Representative Huddleston, Alabama, proposes to provide a system of federal old-age pensions.

## Government Services.

## Openings for Physicians in Conservation Corps

Announcement is made of vacancies on the medical staff of the Missouri-Kansas district of the Civilian Conservation Corps, with headquarters at Fort Leavenworth, Kan. Recent graduates of class A medical schools are preferred, but physicians with extended civilian practice experience are acceptable. All correspondence should be addressed to the district surgeon, Missouri-Kansas District CCC, Fort Leavenworth, Kan.

## Positions Open for Psychiatrists

The U S Civil Service announces open competitive examinations for three positions at St Elizabeth's Hospital, Washington, D C: clinical director (female), at a salary of \$5,600 a year, director of laboratories, \$5,600, and associate psychotherapist (female) \$3,200. The degree of doctor of medicine from a recognized medical school is required for all positions. Applicants for the position of clinical director must show a minimum of five years' experience in psychiatry, which must include at least two years' experience as administrator of a hospital unit of not less than 150 beds treating patients with all types of psychiatric conditions. Applicants for the directorship of laboratories must have had five years' training and experience in research activities in psychiatry and allied subjects. For the third position, three years' specialized work in a psychiatric hospital or clinic operating directly in the field of research and treatment by psychotherapeutic methods is required. Applicants must be in sound physical health and must not have reached their fifty-third birthday. Applications must be filed with the U S Civil Service Commission, Washington, D C, not later than April 20. The necessary forms may be obtained at any first class postoffice, from the Washington office or from the district offices in Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St Louis, St Paul, San Francisco, Honolulu, T H, Balboa Heights, C Z and San Juan, P R.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Feb 29, 1936

#### The Problem of the Diet of the Poor

In an address to the Farmers' Club, Sir John Orr, director of the Imperial Bureau of Animal Nutrition and a leading authority on this subject, attempted to reconcile the interests of the poor, who want cheap food, with those of the farmers, who want good prices. With the object of raising prices, he said, tariffs and quotas had been applied to imports, and agriculture had been given powers to limit the amounts of home-produced foods and to fix minimum prices. These powers carried grave responsibilities. If they were fully developed, 7 per cent of the population would control the food supply of the remaining 93. Those exercising these powers must therefore think not only of the wholesale price that would make farming remunerative but also of the retail price within the reach of all consumers. A recent investigation showed that the diets of the poorer classes were deficient in substances required for health. To bring the diet of the poorer half of the population up to the standard required, the consumption of eggs, fruit, vegetables and meat should be increased from 12 to 25 per cent. To bring their diet up to that of the well-to-do would require double that increase.

#### SUBSIDIZED CONSUMPTION

Sir John Orr paid a tribute to what had been done in organizing agriculture, especially in connection with marketing, and to the government, which took office when the world economic crisis was at its worst. The one thing needed was better prices to give the farmer more money. Where was the money to come from? If what he said with regard to the health aspect was true, it could not come from rise in the price of food unless there was a big rise in unemployment benefit and in the wages of the poorest paid workers. If there could be a subsidized national food policy in the interests both of agriculture and of health, agriculture could be developed along the lines of increasing the production of foodstuffs of special health value. The policy of buying health and making a prosperous countryside by spending more money on food would reconcile the apparently conflicting interests of the farmer and the poor who must have cheap food.

In moving a vote of thanks to Sir John Orr, Lord Bledisloe, a well known agriculturist, said that he had painted a picture of underfeeding in a land of glutted food markets which was no credit to our national organization. Let the government ascertain national food requirements and the sources from which they could be best obtained on an economic basis and then by some form of protection or guaranty assure to the efficient producer a reasonable margin of profit.

#### Snake Venom as a Hemostatic

The coagulant action of certain snake venoms on blood is well known. This led to the suggestion by Dr Hamilton Hartridge, F.R.S., professor of physiology at St Bartholomew's Hospital, that snake venom might be of value in the treatment of hemophilic hemorrhage. R. G. Macfarlane, demonstrator of pathology in the hospital, and Burgess Barnett, curator of reptiles in the Zoological Gardens, accordingly made an investigation (*Lancet* 2 985 [Nov 3] 1934) into the action of various venoms on hemophilic blood. Their most striking results were obtained with *Vipera russelli*. One drop of a 1:1000 solution of the dried venom added to 10 drops of hemophilic blood produced clotting in seventeen seconds, while spontaneous clotting took thirty-five minutes. Moreover, the clot was tough and elastic,

in contrast to the soft ineffective clot of hemophilia. A dilution of 1:10,000 or even 1:100,000 was found to have a clotting time sufficient for practical purposes—about sixty seconds. The action of the powerful toxins in the venom is negligible in the 1:1,000 solution. Complete hemostasis by the local application of the 1:10,000 solution was secured almost immediately to stop hemorrhage after tonsillectomy and hemorrhage in hemophilic patients following dental extraction.

At the recent meeting of the Odontological Section of the Royal Society of Medicine J. D. Cambrook, assistant dental surgeon at St Bartholomew's Hospital, reported his results from this treatment. He pointed out that it was necessary to sterilize the venom. As heat destroys the coagulant, sterilization was accomplished by filtration. At first the venom was put up in solution, but this was found to be unstable unless kept in a refrigerator. The difficulty was overcome by evaporating the venom with saline solution under reduced pressure, so that addition of water gave a 1:10,000 dilution in physiologic solution of sodium chloride. Thus a stable sterile product was secured and it is this which is now used. The action of the venom in so markedly diminishing the coagulation time, not only of hemophilic but of any blood, is not well understood.

Mr Cambrook has used the venom in more than fifty cases of dental hemorrhage arising from different causes, including several cases in hemophilic patients. If there is a history of hemorrhage he removes teeth under local anesthesia, as this allows early manipulation of the wound without pain. Block anesthesia is preferable, as injection near the socket causes some local damage. After the extraction a short, squat plug of absorbent cotton is soaked in hot venom. Pressure is applied only to the edges of the socket and not down into the socket, so that the plug becomes mushroom shaped and acts as a mechanical obstacle to the flow of blood. The pressure on the plug squeezes out the venom and mixes it with the blood in the socket, so as to form a firm clot. The plug is left in position until it falls out, and if hemorrhage occurs another plug is substituted.

#### The Dangers of Aminopyrine

Another inquest has again called attention to the dangers of aminopyrine, mentioned in a previous letter. The deceased was a man, aged 67, who suffered from asthma and bronchitis, for which he had obtained relief by taking tablets containing aminopyrine. He died after taking eight tablets of the preparation, in which he had great confidence. There was nothing on the bottle warning against taking too many. The instructions were that one or two should be taken when required. In giving evidence the government pathologist, Sir Bernard Spilsbury, said: "Pyramidon is a drug which has a proper use, but the danger lies in cases of idiosyncrasy. People take these tablets for a long time with impunity and then the symptoms develop. The benefits obtained from the drug give a false sense of confidence." A representative of the makers of the tablets said that steps had been taken to exclude the drug from the preparation, which now "would be equally efficacious and less harmful." The coroner said that after May 1 the drug would be on the dangerous list, rendering its promiscuous sale more or less impossible. It was taking the drug without physician's orders that constituted the danger. Some people seemed unable to take aminopyrine with safety.

#### Milking Machines and Mastitis

At a meeting of the Research Committee of the Royal Agricultural Society, Dr F. C. Minett made a report on milking machines and their relation to mastitis in cows. A herd of 130 Avshire cows has been under constant supervision of the Institute of Animal Pathology for five years. During this time only a small proportion was affected with the ordinary chronic

and contagious form of streptococcic mastitis, but there were numerous cases of acute mastitis due to a streptococcus different from that causing the chronic form. It was suspected that the fault lay with the milking machine, and after consultation with the maker the milking vacuum was reduced from 15 to 13 inches. This slightly increased the milking time, but since the change, three months ago, no further cases of mastitis have occurred. During the previous nine months there were at least twenty-one cases. In the past the installation of a milking machine for herds previously milked by hand has often been followed by an outbreak of mastitis and the machine has been blamed for causing or spreading this. The truth appears to be that the ordinary chronic mastitis is widespread in a subclinical form, which remains so as long as the cows are milked by hand, but with the change in the method of milking the mastitis becomes apparent. If the udders are really healthy, the system of milking will have no effect.

### Veterinary Help for Animals in Abyssinia

The Royal Society for the Prevention of Cruelty to Animals has made an appeal for help for the animals, which must endure terrible sufferings in the war in Abyssinia, as there is no veterinary service. During the great war the society collected nearly \$1,250,000 and spent it on British sick and wounded horses. In an appeal for funds, published in the *Times*, the society suggests that the need now is greater in one way, as the Abyssinians have made no provision for the care of their animals.

### Hyperparathyroidism

Leriche has published in the *Gazette des hopitaux* his paper on surgery of the parathyroids, read at the international congress in Egypt. He reviews the indications for excision of the parathyroids, which he performed with Jung in thirty-five cases. In Recklinghausen's disease, which is an ankylosing polyarthritis, Leriche is somewhat hesitant, although in favor of intervention. Scleroderma, in his opinion, is the cutaneous expression of hyperparathyroidism. In scleroderma the skin, like many other organs, has an abnormal calcium content, and the bones are rarefied. The therapeutic results of excision are often good, and some cases have remained cured for ten years. Leriche advises, in the worst forms, intervention on the sympathetic system together with ablation of the parathyroids. There are in scleroderma, vasoconstrictive lesions which sympathectomy influence. Moreover, ablation of endocrine glands always has some effect on the paravertebral and prevertebral ganglions. In 1932 Leriche pointed out that surgery of the parathyroids must be looked on as surgery of interrelated tissues. This view is now confirmed. The maintenance of the calcium level in the blood is constantly insured by borrowing calcium from the bones, the process being controlled by the parathyroids. So the parathyroid hormone regulates calcium metabolism. Experimental hyperparathyroidism leads to bone decalcification, to calcemia and phosphatemia, and to metastatic calcifications of the skin and arteries, but only diffuse decalcification of the bones, with or without metastatic calcification, allows a diagnosis of hyperparathyroidism. Many of the diseases must be now studied from the parathyroid angle, especially those in which metastatic calcifications exist, such as calcinosis and gout. On the other hand, in case of hypoparathyroidism Leriche proposes to reactivate the deficient parenchyma by producing vasodilatation. In three cases of tetany, which is the clinical expression of hypoparathyroidism, Leriche tried ablation of the superior cervical ganglion of the sympathetic. The results were promising.

### The New Leprosy Center in South America

There are in South America two large leprosy areas in the North, Guiana, Venezuela, Colombia and Ecuador, in the South, Brazil, Argentina and Paraguay. In Brazil, it is estimated there are at least 50,000 lepers. The Brazilian government has just founded, with the assistance of the League of Nations, a well equipped leprosy center in Rio de Janeiro. Its director will be Professor Edward Rebello of the Rio de Janeiro Faculty of Medicine. Contracts were made with various health organizations, including the Institut Oswaldo Cruz, the government health services and leprosy hospitals, to insure the cooperation of every important leprosy service with the new center. The most notable organization against leprosy heretofore has been the São Paulo Service, which required the isolation of lepers in five hospitals or colonies. The new center will cost about 10 million francs, donated by the Brazilian government, the League of Nations and a French-Brazilian citizen, M. Guinle. The center will cooperate with any South American nation concerned with the leprosy problem.

### Dermatology and Pathology

In the congress at Budapest, last year, Dr. Darier read a paper on the history of dermatology during the last fifty years, pointing out that dermatology was an unusual field for those interested in general pathology. Darier deplored the confusion of terms that prevails in dermatology. There is urgent need of principles, exact terminology and standardization in this branch of medical science. Darier discussed the need of making an exhaustive diagnosis. His considerations went beyond the bounds of dermatology, into general pathology. But his views are in opposition to those of Loeper, as expressed in a recent inaugural address. Loeper aims to explain everything by chemical specificity, Darier by individual reactions. Their views embody the two great tendencies of medicine either toward the disease or toward the patient. As usual, the truth is probably in between these extremes, but it is interesting to witness controversies between exponents of conflicting theories.

### Federal Commission for the Protection of German Blood

The so-called Nuremberg laws make the conclusion of marriage between citizens having two Jewish grandparents and Germans or non-German Aryans, or citizens having but one Jewish grandparent, subject to the approval of the minister of the interior and of the deputy to the fuhrer. A federal commission for approval of marriages has been organized for examination of petitions.

The information utilized by this commission in arriving at its decisions is prepared, after specific investigations, by the high administrative bodies throughout the reich (provincial governors, district prefects, high officials of the independent German states) with which the petitions for approval are lodged. These administrative officials gather what information they can with regard to the petitioner's physical, mental and moral qualities, his participation in the World War, his political reliability and his racial character. In addition, an investigation of the petitioner's family history is undertaken in order to ascertain for how long the family has been domiciled in Germany, what professions or trades its members have followed, whether or not required terms of service in the German armed forces have been fulfilled, and whether or not the family, especially if of German blood, has participated in German cultural life. The administrative body also subjects the petitioner to a physical examination by the health authorities. This examination is especially concerned with racial characteristics. The

administrative body must then obtain, appended to the transcript of the results of this examination, the recommendation of the director of the local public health bureau of the National Socialist German Workers Party. This local director transmits his opinion to the district supervisor of the same bureau, who returns it to the administrative body after appending his own recommendation.

The federal commission consists of seven regular members, four of whom at the present time are physicians, and, in addition, seven alternate members, one of whom is a physician. The commission, on its initiative, can make investigations, summon experts and, which is more important, order the petitioner to appear in person before it. The conclusions of the commission are in the form of recommendations. The power of approval or rejection rests with the minister of the interior and the deputy of the fuhrer. A fee of 10 marks is charged for the granting or denial of a petition, moreover, the costs in each individual case are assessed against the petitioner.

### First Aid for Sudden Illness

A poster emanating from the Insurance Physicians' Association, the Hospital Association and the Central Municipal Bureau of Health was recently affixed to buildings in Berlin. This notice directed the population, in the event of sudden illness, if the stricken person's regular physician could not be summoned, to call on a "first aid physician (*bereitschaftsarzt*)" of the League of German Physicians (an exclusively Aryan organization). The municipal first aid stations (*rettungsstellen*) must henceforth be resorted to only in emergency cases in which it is a matter of life and death. In all other cases these stations shall either refuse to treat the sick person or charge him for such treatment, as sick insurance will not cover the cost of such service. Each person now receives prompt medical attention, in the event of sudden illness, from a first aid physician. Much unnecessary effort and expense are saved in this manner. This regulation is important because it means that, since the insurance physicians' organization seldom grants fees to authorized member physicians, only in exceptional cases can an unauthorized physician now receive a fee from the organization. This regulation must be applied also in the first aid stations. Among other noteworthy advantages of the new rule, it removes a burden of steadily mounting expense from these stations.

Every practicing physician belonging to the National Socialist Physicians' League or the Berlin League of German Physicians is obliged to participate in the first aid service unless incapacitated by age or illness. Hours of night duty are from 7 p. m. to 7:30 a. m., of Sunday duty from 8 a. m. to midnight. While in service duty a physician can only exceptionally make a professional visit in the neighborhood, even to one of his own patients. A pamphlet, appearing quarterly, will contain a schedule of all first aid physicians and the dates assigned them for service.

### Violations of Venereal Disease Legislation

The operation of the antivenereal disease law of Feb. 18, 1927, in terms of adjudicated cases of violation may be studied in data for the first five year period from 1928 to 1932. The provision most frequently violated was that which prohibits a person with a contagious venereal disease from indulging in coitus. Since 1928 the number of convicted violators of this clause has decreased from 292 in 1928 to 206 in 1932. The number of females convicted was nearly three times that of the males. Punishment for this particular offense consisted generally of prison terms of less than three months. Fines were less frequently imposed. The proportion of offenders under the age of 18 amounted to about 5 per cent and was therefore almost as low as the corresponding proportion shown by figures for the entire reich on the age-group distribution of venereal

disease. Among juvenile offenders the female sex preponderates by a wide margin, of a total of sixty young persons convicted from 1928 to 1932 only three were males. A majority of the juvenile offenders received suspended sentences. Comparatively seldom did a court hear charges against venereal disease sufferers who had married without informing the marriage partner of their condition. In the five year period under discussion only nine such cases were disposed of, convictions resulting in seven of these cases (four men, three women). From these meager figures no opinion can be formed as to the incidence of venereal disease in persons contracting marriage. During the same five years, 576 persons not licensed to practice medicine were charged with the illegal treatment of venereal diseases, of this number, 491 (including seventy-nine females) were convicted. Only thirty-three received prison sentences, fines were imposed on the others. In the same period fourteen physicians were convicted of the unethical public advertising of the treatment of venereal diseases. In all of these cases, fines were imposed. Sixty-five persons were found guilty of having advertised alleged cures or palliatives for venereal diseases.

According to data from the state bureau of health, made public, as was the preceding, by Dr. Pohlen, twenty-six midwives contracted infections from newly delivered or lying-in women during the years 1929 to 1934.

### The Blood and Spinal Fluid in Barbituric Acid Poisoning

Drs. Voss and Fretwurst of Brambeck Hospital, Hamburg, have undertaken in ten cases of barbitol poisoning and one of phenobarbital poisoning the study of comparative quantitative determinations of the barbituric acid content in the erythrocytes, blood plasma, cerebrospinal fluid and urine. No barbituric acid derivants were present in the erythrocytes. On the other hand, substantial quantities of barbitol and of phenobarbital could be isolated in the plasma, cerebrospinal fluid and urine. The slow passage of the barbituric acid derivatives from both erythrocytes and fluids makes manifest, according to the interpretation of the authors, that it is a question of simple dialysis. The rest of the spinal fluid observations were for the most part normal. A considerable increase in the spinal fluid pressure was in no case observed. Only one case (severe barbitol poisoning) showed slight increase in albumin content and a slight increase in the number of cells.

### Treatment of Joint, Gland and Bone Tuberculosis

In a lecture before the Society of Physicians, Dr. Max Jerusalem discussed the problem of surgery in tuberculosis other than pulmonary. Forty years ago two conflicting attitudes existed with regard to this question: one group called conservative, and another group more favorable toward operations. Soon it was perceived that these questions must be viewed in the light of individual differences not only between patients but between physicians as well. Important too is the nature of the disease, whether fibrous or destructive. In the last decade the conservative procedure has gained many adherents particularly as the importance of heliotherapy and roentgenotherapy has been recognized. The heliotherapeutic stations in Switzerland are well known. Nevertheless in recent years many Swiss specialists have rather turned to surgical treatment, which, if the indication is correct, may save much time and effect speedier cures. Dr. Jerusalem, who has gained vast experience in tuberculosis as a sick insurance physician, states his guiding principles as follows: Treatment of bone, gland and joint tuberculosis should be predominantly and almost entirely conservative. Selection of therapeutic measures must

depend on the particular conditions presented in each separate case. When operative treatment is indicated, one should be guided by the following suggestions: 1 Isolated, not unduly large, firm, movable glandular tumors on the axillae or neck, when refractory to radiotherapy, should be extirpated. 2 Wide electrosurgical opening of small cold abscesses on the thorax or neck should be done, evacuation without drainage (in order to avoid mixed infection), then complete suture and, after primary healing, roentgenotherapy. 3 Bone sequestrums should be removed only if spontaneously projecting outward in a necrotic state or as foreign bodies lying in the soft parts. 4 Fungus on tendon sheath that may cause liquefaction should be treated as under 2. 5 Para-articular bone areas may occasionally be removed. This requires a large amount of skill. 6 Resection of the knee joint should be done in adults presenting a shrunken fibrous capsular fungus with erosion of the cartilaginous covering. 7 Amputation should be done in cases of progressive joint processes in aged patients; otherwise treatment should be as conservative as possible. 8 After successful treatment, osteotomy and arthroplasty should be chosen as a secondary operation for the purpose of correcting posture. 9 Contraindicated are simple incision and drainage of a cold abscess, scraping of central bone sequestrums, extirpation of multiple diffuse glands on the neck or axillae and resection of carious ribs, as well as resection of all joints with the exception of the knee joint as indicated.

#### Deaths of Professors Busson and Maresch

In the first days of the new year the Vienna Faculty of Medicine suffered two severe losses. First, a great serologist and bacteriologist, Prof. Dr. Bruno Busson, aged 56, died. At an early age he obtained the doctorate in both philosophy and medicine and then began his career as an assistant to Professor Prausnitz at the Institute of Hygiene, Graz. In 1911 he came to Vienna to work under Professor Paltauf at the Serotherapeutic Institute. During the war he was in charge of a mobile laboratory and thanks chiefly to his efforts no diseases or epidemics were able to gain a foothold among the Austrian troops, even in regions where the surrounding sanitary conditions were of the worst (the Balkans, Russian Poland, Turkey). After the war he resumed his duties at the Vienna Institute and was above all active as director of the Serum Control Center. All serums and vaccines, imported or domestic, were examined by this center. Dr. Busson also headed the institute founded by Paltauf for protective inoculation against rabies. His scientific labors were concerned with the problems of immunization and of experimental medicine.

A few days later Dr. Rudolf Maresch, director of the Pathologic-Anatomic Institute of the University of Vienna, died. Of German-Bohemian extraction, he took his degree at Prague, where he became assistant under Professor Rabe in the Institute of Anatomy. Subsequently he came to Vienna and first worked under Gussenbauer and later under Professor Chrobak at the woman's clinic. Still later he became active in Professor Chiari's Institute of Pathologic Anatomy and finally was appointed senior pathologist for two of the largest hospitals in Vienna. His scientific activity at the University of Vienna gained for him the titles of docent (1911), assistant professor (1916) and professor in ordinary of pathologic anatomy (1923). The internal secretions were his particular interest, although he was also concerned with gynecology and the digestive tract. That he was an able organizer, the construction of the institute's new building under his direction bears ample testimony. The largest lecture hall of the University of Vienna, from the 400 comfortable seats of which the students obtain an adequate view of the specimens, also owes its existence to him. In addition he organized an extremely comprehensive museum, which is one of the sights of Vienna, and placed it at the disposal of the students. Professor Maresch

filled all the high posts within the gift of the university, he was successively dean, rector and president of the Vienna Academy of Science. For the past year he had been afflicted with a carcinoma of the bronchus, which caused his death at the age of 68. His school has attained preeminence as the result of the great number of his former pupils who fill important professional posts throughout middle Europe.

#### Reunion of Physicians Pertaining to Aviation Medicine

The first national assembly on aviation medicine was recently held in Milan with Professor Cornelli presiding. Professor Herlitzka, a physiologist of the University of Turin, spoke on physiology in high altitudes. The atmosphere can be divided into four zones according to the effects that atmospheric pressure causes on the organism of aviators as they fly into high altitudes. The first zone includes the atmosphere from sea level to an altitude of 4,000 or 6,000 meters. The barometric pressure in this zone ranges between 460 and 400 mm of mercury. Within these limits no noticeable organic disturbances are felt. The second zone reaches an altitude of 8,000 meters above sea level. Its barometric pressure ranges between 250 and 200 mm. This zone is characterized by causing the so-called disease of the altitudes. The third zone reaches an altitude of 14,500 meters above sea level. Its barometric pressure is 95 mm. The preservation of life at this altitude is possible only if respiration is made with pure oxygen or a proper mixture of gases. Above the third zone, that is, in the last and highest layer of the atmosphere, aviation is possible only by isolating the aviator from the surrounding atmosphere by means of an air-tight cabin or of an apparatus similar to a diver's dress, provided in each case with the oxygen supply. The most noticeable deficiency that aviators find in reaching great altitudes is that the diminution of the partial pressure of oxygen of the ambient air causes a diminution also of the tension of the oxygen of the alveolar air, which is the agent for the regulation of the absorption of gas by the organism. However, it has been proved through the experiments of Mosso, Talenti and Margaria that the effects of a low barometric pressure are due not only to the lowering of the partial pressure of oxygen but also to the lowering of carbon dioxide in the blood, which is the agent that causes stimulation of the nervous centers of respiration. The altitude of 14,433 meters above sea level, which Donati reached in his record flight, marks a limit that will be surpassed only by fliers using the air-tight cabin. An altitude of 12,000 or 13,000 meters above sea level can be considered the limit of safety in flying of long duration into great altitudes, provided the aviators breathe a mixture of oxygen.

Professor Gemelli, dean of the Catholic university of Milan, discussed the functions of the pilot from a psychophysiological angle, in relation to the development of aviation. The position of the pilot during flying was first given attention. Orientation with relation to remote points, according to the work performed by Clapadere, Gemelli and Jaccard, is a complicated process in the verification of which memory, attention, comparison and discrimination take a part. The capacity of remote orientation is scanty in human beings. Orientation is lost during flying, such as is the case when one wanders into the wilderness or into the deserts and there is no specific sense or instinct to serve as a guide. The psychic processes use almost exclusively the information given by sight. The latter, however, has a limited field in aviation and errors and illusions are rather frequent. Sight gives orientation when a person moves at a certain speed in accordance to one's proper means of locomotion. At the speed and altitude at which one moves during flying, however, it fails to do so, and the more intense the degree of these two

factors the greater the difficulties related to orientation. That is the reason why orientation should be controlled by the use of proper mechanical apparatus and not by sight. In this connection the selection of candidates is based on their ability in using the necessary apparatus and giving a correct interpretation to the geographic, topographic and meteorological data by which the position of the airship in relation to the surface of the earth can be determined. Far different are the aptitudes required for pilots of military airplanes, especially pursuit planes. This is a problem which deserves especial consideration.

### Zone of Quiet for Clinics

A session was recently held in the senate to discuss a law tending to control the noise caused by automobiles in the streets. Dr. Devoto of the Clinica del Lavoro of Milan pointed out the importance of such a law to the public welfare, especially the sick. He also pointed out how advisable it would be to surround clinics, hospitals and schools that are located in the city and cannot be moved to less noisy places by a zone of quiet.

### Report on Changes in the Medical System

The Japan Medical Association has presented the long anticipated report on the reform of the general medical system in this country. The first necessity, the report says, is to secure complete unity of the governmental administrative units. The administrative medical setup at present is separated roughly into three large sections, under the control of the Home Office, the Communication Office or the Agricultural and Forestry Office. The lack of unity among those three offices has caused many controversies affecting the smooth working of the medical administration. The most urgent need is to authorize the Health Office to deal with all medical administration independently of the other offices. The second important problem is that of the relation between the family doctor and the patients which is undergoing rapid changes as the social tide flows now this way and now that. The old system of the family doctor has many advantages over the new relation, which tends to convert the relation into that of a commercial transaction. To be humane and not to be inhumane is an important part in medical treatment. The family doctor is well acquainted with the domestic conditions of every family, which aids in promoting mutual understanding. Any family doctor always has been and always will be glad to give his time to patients when required. The patient has the right of free choice of physician and that fact has been convenient to those whose daily life has not been systematized. When a patient is temporarily unable to pay a bill, the family practitioner will wait without causing much trouble. Such an inseparable relationship naturally leads to doctors rather than government officials doing social relief work. Therefore the fundamental medical system should be based on the old system of the family doctor.

On the other hand, the development of various health unions is the present social tendency and the medical association must recognize their value and help their sound development. The most essential factor in those health bodies is a system permitting the free choice of physician by the members. Every new plan for medical treatment should be based on the original object instead of support through fees for treatment. For instance, the hospitals attached to medical colleges or universities should again be hospitals where clinical research is done without any idea of profit. The public or charity hospitals should treat indigent patients free at present some of them are trying to raise more or less money by the treatment. At the same time, hospitals and clinics should be established and managed by medical men to avoid the commercialization of medicine. Thirdly, the distribution of doctors should be regu-

lated by the government, and where there is no doctor in remote places a government doctor should be available or the local community should have a doctor at its own expense and those doctors should be pensioned when they retire. In order to have its own doctor, the locality may send a medical student to college and pay his school expenses. Next in importance is the rationalization of medical fees, which should be on a different plane from commercial transactions. The medical fee should be estimated by the kind of sickness, that is, by the amount of medical labor, but the financial condition of the patients should be taken into consideration. As this fee has some relation to social economy and the national health, a standard fee is essential to avoid businesslike competitive methods. Those who are too poor to pay the medical fee are to be aided through relief societies.

It is no less important to readjust and control the various relief projects and bring them under the central authorities. At present they are independent and so the initial cost and the expense of their maintenance prevent them from being adequately equipped. Much more equipment is needed by the various public bodies where chief work must be preventive medicine. The idea of sanitation should prevail among the people in every home, and that is best brought about by the family physician. The promotion of school hygiene also is better achieved when every practitioner participates in it.

Next comes the problem of medicines and chemicals, which have recently increased greatly in number. The value of some of them is likely to be overestimated through the lack of proper institutes for testing them. A research department should be established to examine them and regulate their production and price, even the price of those manufactured in government factories is prone to be high when sold through middlemen or brokers.

Lastly, it is desirable for the government to establish a fixed policy in medical education. At present there is a tendency toward an overproduction of medical men. Every student after graduation from medical college should pursue clinical training for a reasonable period, and then those who wish to be specialists should be trained for a longer period in clinics. The medical association must have its own research institutes for this purpose.

### The Increase in Physicians

The number of medical men in 1934 has been officially reported as 55,086, an increase of 2,224 over the previous year. In 1932 there were 50,069. Those in practice numbered 49,308, a decrease of 543 as compared with those in 1933. This decrease is believed to have been due to the revision of the medical law, which partly limited the establishment of new clinics. On an average a population of 1,383 had one practitioner, in cities 803 in smaller localities 2,082. The number of dentists was 18,998, while in 1933 it was 17,984, an increase of 1,014. Of these 17,622 were in practice. 258 dentists to 10,000 population were in practice. The number of pharmacutists was 23,283 an increase of 1,481, as compared with the previous year. The number of midwives was 58,270 and of nurses 102,921.

### Increase in Beds for Lepers

The Home Office has announced a ten year program of raising the number of beds for lepers to 10,000. The present number of beds is 6,450 in all the country while the number of lepers is over 15,000.

### Personals

Dr. Minoru Sasaki, assistant professor in the Manchurian Medical College, has been appointed chief professor in the otorhinolaryngologic section of the Kyushu Imperial University.

Dr. I. Inada, dean of the medical college of the Manchurian Railway Company, was obliged to retire and Prof. Dr. S. Kubota will be the new dean.

## Marriages

WILLIAM MARION HAIL, Bay St Louis, Miss, to Miss Ella Robinson of Centreville, February 19

JOHN WILLIAM DRAPER JR to Miss Mary Willcox Ayres, both of New York, February 7

BERNARD LEE MELTON to Miss Marie Rhea Linsenmeyer both of Phoenix, Ariz, in February

HERMAN I SWITZES, New York, to Miss Lillian Tepper of Washington, D C, March 29

BANNISTER LESTER HARBIN to Miss Jane E Goodwin both of Rome, Ga, February 11

RAYMOND J KENNEDY to Miss Bernice Elaine Sitar both of Joliet, Ill, February 11

JOSEPH H PARKS, Monroe La, to Miss Vina Gallman of Rayville, January 18

WALTER M KRAUS to Miss Victoria Bowe both of New York, Dec 20, 1935

RICHARD L I KIMM to Miss Margaret Pennington both of Chicago, March 23

HARRY PARKS to Miss Sylvia Mendel, both of Atlanta, Ga, recently

## Deaths

Charles Jefferson Miller ♂ professor of gynecology, Tulane University of Louisiana School of Medicine, New Orleans, died, March 21, of coronary thrombosis, aged 62. Dr Miller was born in Winchester, Tenn, Feb 9 1874. He attended Terrill College and the University of the South Sewanee, Tenn, and received his medical degree from the University of Tennessee Medical Department, Nashville in 1893. After serving an internship at the Nashville City Hospital, he did postgraduate work in London and Berlin. In 1911 he was appointed professor of gynecology at Tulane University of Louisiana School of Medicine and later professor of abdominal surgery at the graduate school of medicine. From 1908 to 1911 he was secretary of the Section on Obstetrics, Gynecology and Abdominal Surgery, then known as the Section on Obstetrics and Diseases of Women, and chairman from 1911 to 1912 of the section, then known as Obstetrics and Gynecology, of the American Medical Association. He was a founder, past president, a member of the board of regents and a life member of the American College of Surgeons, member and past president of the American Gynecological Society, Southern Surgical Association and the Orleans Parish Medical Society, and president of the Southeastern Surgical Congress. Dr Miller was a senior visiting surgeon to the Charity Hospital, New Orleans, and chief of the department of gynecology, Touro Infirmary, and formerly a member of the board of control of the Leper Home of Louisiana now known as the United States Marine Hospital (National Leprosarium). He was also a member of the Medical Reserve Corps of the U S Army, and president of the Howard Memorial Library.

Charles Louis Chassaignac, New Orleans, Tulane University of Louisiana Medical Department, New Orleans 1883, formerly professor of genito-urinary diseases and president of the New Orleans Polyclinic, and dean and professor of genito-urinary and rectal diseases after that school became the Tulane University Graduate School of Medicine, member of the House of Delegates of the American Medical Association in 1905, 1906 and 1910, member and past president of the Louisiana State Medical Society, past president and secretary of the Orleans Parish Medical Society, served as a member of the board of appeals of the draft board during the World War for eight years superintendent of the Eye, Ear, Nose and Throat Hospital, at one time consulting surgeon to the Charity Hospital, editor of the *New Orleans Medical and Surgical Journal* 1896-1922 translated from the French the monograph by Touatre on yellow fever, aged 74, died March 21.

Edward Bradford Dench ♂ New York, College of Physicians and Surgeons Medical Department of Columbia College, New York, 1885, professor of otology, University and Bellevue Hospital Medical College from 1898 to 1930, at which time he became professor emeritus, member and past president of the American Laryngological, Rhinological and Otolological Society, past president of the American Otolological Society and the New York Otolological Society, honorary member of

the Royal Society of Medicine of London and the Austrian Otolological Society, fellow of the American College of Surgeons, served during the World War, consulting aural surgeon to the New York Eye and Ear Infirmary, consulting otologist to St Luke's Hospital and New York Orthopedic Dispensary and Hospital, aged 72, died, February 21, of cerebral hemorrhage.

Sylvester Richard Leahy ♂ New York, Yale University School of Medicine, New Haven, 1905, at one time instructor in neurology, Columbia University College of Physicians and Surgeons, and instructor in psychiatry and clinical professor of psychiatry, University and Bellevue Hospital Medical College, member of the American Psychiatric Association, secretary and past president of the New York Society for Clinical Psychiatry, police surgeon, formerly attending neurologist to the Holy Family and St Peter's hospitals, consulting neurologist to the Brooklyn State and Kings Park hospitals, director of the mental clinic, Catholic Charities, and associate visiting neurologist and psychiatrist, St Vincent's Hospital, aged 53, died January 29 of heart disease, in the Harkness Pavilion of the Columbia Presbyterian Medical Center.

Henry Ware Cattell, Burlington, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1887, demonstrator of morbid anatomy at his alma mater 1892-1897, director of the Aver Chemical Laboratory, Pennsylvania Hospital, Philadelphia, 1899-1901, served during the World War, at various times pathologist to the Blockley Hospital, now the Philadelphia General Hospital, and the Presbyterian Hospital, Philadelphia, in 1929 delegate to the International Congress of Military Medicine and Pharmacy in London, editor of *International Clinics*, 1900-1903, 1910-1916 1922-1932, editor of 'Lippincott's Medical Dictionary' in 1910 and 1913, translator of Ziegler's *Special Pathological Anatomy*, 1896-1897, aged 73, died, March 8, in the Veterans Administration Facility, Washington, D C of heart disease.

Arthur David Holmes, Detroit, McGill University Faculty of Medicine, Montreal, Que, Canada 1889, member of the House of Delegates of the American Medical Association, 1911-1912 for many years trustee and past president of the Wayne County Medical Society, president of the Detroit Academy of Medicine 1901-1902, vice president of the Mississippi Valley Medical Association, 1911-1912, and trustee of the Detroit Tuberculosis Society, fellow of the American College of Physicians, formerly professor of otology, rhinology and physical diagnosis Detroit College of Medicine and Surgery, served during the World War, consultant to the Children's Hospital and the Woman's Hospital, aged 72, died, February 20, of cerebral hemorrhage.

Donald Putnam Abbott ♂ Chicago, Rush Medical College, Chicago, 1910, associate clinical professor of medicine at his alma mater, intern at the Cook County Hospital, 1910-1911, did graduate work in Vienna in 1914, member of the Central Society for Clinical Research, Institute of Medicine of Chicago, and the Society of Internal Medicine of Chicago, served in the medical corps of the U S Army in France during the World War, author of the chapter on "Carcinoma of the Stomach" in Tice's *System of Medicine*, aged 51, attending physician to the Presbyterian Hospital where he died, March 26, of pulmonary embolus following bronchopneumonia.

James Sproat Green ♂ Elizabeth, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, past president of the Medical Society of New Jersey and the Union County Medical Society, fellow of the American College of Surgeons, served during the World War, formerly member of the city board of health, consulting surgeon to St Elizabeth Hospital, Elizabeth General Hospital, Elizabeth, Bonnie Burn Sanatorium, Scotch Plains, and the Rahway (N J) Hospital, aged 71, died, January 30, of carcinoma of the stomach.

James Clement Harkins, New York, University and Bellevue Hospital Medical College, New York, 1903, member of the Medical Society of the State of New York, at one time adjunct professor of pediatrics, Fordham School of Medicine, served during the World War, member of the medical advisory committee, Department of Hospitals, New York, served in various capacities on the staff of the Fordham Hospital, consulting pediatrician to St Joseph's Hospital, Yonkers, N Y, aged 54, died, February 18, of bronchopneumonia and chronic myocarditis.

Cyrus Burns Craig ♂ New York, Western Reserve University Medical Department, Cleveland, 1911, assistant clinical professor of neurology, Columbia University College of Physicians and Surgeons, member of the American Neurological Association and the Association for Research in Nervous and

Mental Disease, served during the World War, aged 52, consultant in neurology, Fordham Hospital, New York and the Paterson (N J) General Hospital, associate medical director of the Neurological Institute, where he died, February 24, of carcinoma

**Edgar Bright Funkhouser**, Trenton, N J Jefferson Medical College of Philadelphia, 1900 member of the Medical Society of New Jersey past president and secretary of the Mercer County Medical Society member of the American Psychiatric Association, served during the World War, aged 66 senior resident physician at the New Jersey State Hospital, where he died, January 26, of coronary sclerosis

**Patrick Joseph Kennedy**, Long Island City N Y, Queens University Faculty of Medicine Kingston Ont Canada 1911 member of the Medical Society of the State of New York on the staffs of St John's Hospital Long Island City Queens General Hospital Jamaica and the Manhattan Eye and Ear Hospital, New York, aged 49, died, January 21, in Daly's Astoria Sanitarium

**McCluney Radcliffe** Philadelphia University of Pennsylvania Department of Medicine Philadelphia 1882 for many years associated with the Wills Hospital and the Presbyterian Hospital in various positions consulting ophthalmologist to the State Hospital, Norristown trustee of Lafayette College Easton, Pa aged 81, died February 28 of pneumonia

**Charles Dun Pedrick**, Glassboro, N J Medico-Chirurgical College of Philadelphia, 1900, member of the Medical Society of New Jersey, past president of the Gloucester County Medical Society, served during the World War for twenty-one years medical examiner of the public schools of Glassboro aged 73, died January 24, of cerebral hemorrhage

**Samuel Johnson Cogswell**, Derry N H University of Vermont College of Medicine Burlington, 1897, member of the New Hampshire Medical Society, past president of the Rockingham County Medical Society, health officer of Derry on the staff of the Alexander-Eastman Hospital East Derry, aged 60, died January 18 of pneumonia

**Joseph Ellis Skaggs**, Leavenworth Kan University of Louisville (Ky) School of Medicine 1915 member of the Kansas Medical Society president of the Leavenworth County Medical Society formerly county coroner aged 50 on the staff of the Cushing Memorial Hospital, where he died January 20, of carcinoma

**Joseph Anthony Cooke**, Meriden Conn Yale University School of Medicine New Haven, 1897 member of the Connecticut State Medical Society health officer of Meriden formerly mayor aged 69, died January 22 of bronchopneumonia, cerebral hemorrhage and hypertension

**Charlotte Hooper Phillips**, New York Columbia University College of Physicians and Surgeons, New York 1930 member of the Medical Society of the State of New York on the staff of the New York Infirmary for Women and Children aged 31, died January 23 of pneumonia

**Curtis Harrod Thomson**, Seattle, University of Virginia Department of Medicine, Charlottesville, 1897 member of the Washington State Medical Association, secretary of the Washington State Medical Association served during the World War, aged 61, died, March 7

**Fenton Blakemore Whiting**, Richmond Beach Wash Cooper Medical College, San Francisco 1891 member of the Washington State Medical Association fellow of the American College of Surgeons, aged 69, died, January 15 of hypertension and cerebral hemorrhage

**Harold Walter Longwell**, Avoca, N Y University of Buffalo School of Medicine 1929 member of the Medical Society of the State of New York health officer aged 33, died, January 23, in a hospital at Bath of cerebral hemorrhage and chronic nephritis

**Daniel Traverso**, Belmar N J University of Arkansas School of Medicine Little Rock 1926 member of the Medical Society of New Jersey aged 36 on the associate staff of the Pitkin Memorial Hospital, Neptune where he died January 28 of lobar pneumonia

**Frank Brouwer**, Toms River N J Jefferson Medical College of Philadelphia, 1894, member of the Medical Society of New Jersey formerly county coroner on the staff of the Paul Kimball Hospital, Lakewood aged 65 died, January 24, of arteriosclerosis

## Correspondence

### "COPPER AND PIGMENTATION OF SKIN AND HAIR"

*To the Editor*—The editorial "Copper and Pigmentation of Skin and Hair" (*THE JOURNAL*, February 22, p. 629) is the subject of this communication. In a discussion at the meeting of the Illinois Medical Society in 1933 (*Illinois M J* 64:80 [July] 1933) I described the case of a woman, aged 21, seen by Dr. Cleveland White and myself, in whom darkly pigmented moles appeared on the skin following copper therapy. The patient, who had a mild anemia, received ferric ammonium citrate 3 Gm and copper sulfate 15 mg daily for four weeks. The pigmentation appeared two weeks after treatment was begun. The lesions consisted of brown and black pigmented macules and papules varying from the size of a pinpoint to the size of a small pea. They were most numerous on the neck but also occurred on the face, the upper part of the trunk and the extremities.

I saw the patient today, and there has been no tendency for the moles to fade or disappear. The moles on her face (eight in number) were very annoying at first, but she has since become accustomed to them. The patient, who is a registered nurse, is absolutely certain that the pigmentation was a direct result of the copper and iron therapy.

In view of the experimental evidence presented in the editorial, it seems that copper was instrumental in the production of the pigmentation in this patient. If this observation is correct, the indiscriminate use of copper therapy may lead to some embarrassing medicolegal problems.

HOWARD L. ALT, M.D., Chicago

### TREATMENT OF ALCOHOLISM WITH CARBON DIOXIDE-OXYGEN INHALATION

*To the Editor*—I read with interest the paper of Newman and Card (*THE JOURNAL*, February 22, p. 595), in which is reported the experimental investigation of the striking effects obtained by Robinson and myself in the treatment of acute alcoholism with 10 per cent carbon dioxide and 90 per cent oxygen inhalation. In order that the reading medical public may be made aware of the actual value of their report, it should be pointed out that the facts on which they base their conclusion are subject to the following criticisms:

1. In reviewing the literature readily available, references contradicting their opinion are not mentioned. Barach is quoted as stating that the lethal dose of alcohol for rabbits was the same in an atmosphere of oxygen as it was in air. They do not mention that Palthe (*Alcohol Poisoning, Deutsche Zeitschr f. Nervenh.* 92:79-100, 1926) found that the inhalation of oxygen prevented death in rabbits that had been given alcohol in doses that were lethal to control animals.

2. Barach (*Action of Oxygen in Counteracting Alcoholic Intoxication, Am J Physiol* 107:610-615 [March] 1934) is only partially quoted. They do not mention that he gives evidence which in his own words "suggested that the inhalation of oxygen counteracted to some extent the effects of alcohol."

3. Their number of experimental subjects was extremely small, consisting only of two human beings and three dogs.

4. They ran no controls whatever to check their experimental results.

5. Neither of their human subjects was sufficiently intoxicated to produce much more than an odor of alcohol on the breath (Turner, R. G. *Blood Alcohol and Its Relation to Intoxication*

in Man, *Proc Soc Exper Biol & Med* 32:1548 [June] 1935). Turner states that, in general, intoxication is not noticeable in man until the blood alcohol concentration is greater than 0.2 per cent. In Newman and Card's human subjects at the onset of the administration of carbon dioxide and oxygen inhalation the blood alcohol concentration was only 0.2 per cent in the first case and considerably less in the second. In our cases the lowest blood alcohol concentration was 0.338 per cent and the highest 0.654 per cent. It is quite possible that at these higher levels the effect of carbon dioxide and oxygen inhalation is much more marked in human beings than at the low level reported by Newman and Card.

6. They attempt to draw clinical conclusions from dogs—drunken canines—though they state specifically that they are not interested in the clinical point of view.

7. They do not take into account sufficiently the possible effect of carbon dioxide and oxygen inhalation on intracellular oxidation (Wright Samson, *Applied Physiology*, ed. 5, New York: Oxford University Press, 1935).

The title of the paper and its conclusions are misleading in that they suggest that a rational basis for the use of carbon dioxide and oxygen inhalation in acute alcoholism does not exist. The subject deserves more intensive study before the shadow of doubt is cast on the value and efficacy of this therapeutic procedure.

SYDNEY SELFSNICK, M.D., Boston

### NERVOUS COMPLICATIONS FOLLOWING SPINAL ANESTHESIA

*To the Editor*—The report on nervous complications following spinal anesthesia by Brock, Bell and Davison (*THE JOURNAL*, February 8) leads us to suggest a slight change in the technic of spinal anesthesia which we are convinced is of definite value.

The modification that we advise has been employed by us in more than 600 low spinal anesthetics and apparently has afforded the following advantages: 1. It limits the effect of the anesthetic to the lower part of the spinal cord, thereby preventing fall in blood pressure and vomiting, which up to the time we began the technic now employed had been a rather frequent and disturbing factor. 2. Localization of the anesthesia makes it possible to lessen by about one third the amount ordinarily used. 3. There have been practically no nervous complications following spinal anesthesia obtained in this manner. All anesthetics in our group were for low operations such as external urethrotomy, transurethral resections of vesical neck obstructions and fulguration of extensive tumors of the bladder. Higher and satisfactory anesthesia might be obtained by the same technic except that the anesthetic in such cases should be injected at a higher point. A preparation of procaine hydrochloride with strychnine sulfate known as spinocaine was the only type anesthetic used. This preparation is lighter than the spinal fluid which feature is most essential to our technic. After the needle has been inserted into the spinal canal and the spinal fluid begins to flow the table is tilted to lower the patient's head 15 degrees before the anesthetic is injected. Then the syringe containing the anesthetic is attached to the needle and an equal volume of spinal fluid is drawn into the syringe and mixed with it. Then two thirds of this mixture is injected into the canal and again some fluid is withdrawn, this time only about one half the volume. This mixture is then injected into the canal. We have attributed our lack of nervous complications to this diluting admixture of spinal fluid with the anesthetic before the injection. The solution reaching the nerve roots is thereby rendered less concentrated and hence less irritating than if it were not so diluted.

The lowering of the head we are convinced affords a valuable method of localizing the anesthetic to the lower part of the

spinal canal When the head is lowered the mild venous congestion causes an increase in intracranial pressure, which prevents any flow of anesthetic toward the head after the injection. The anesthetic, being lighter than spinal fluid, tends to flow toward the lower end of the spinal canal.

Soon after the adoption of this plan we thought it was probably only a coincidence that we no longer saw the reactions that we hitherto had attributed to idiosyncrasies and so on. The striking features incident to this technic were the exceedingly small number who vomited and the maintenance of satisfactory blood pressure. Usually within about ten minutes anesthesia is complete. If not, perhaps not more than five minutes' additional waiting may be required.

If Drs. Brock, Bell and Davison will try this technic we feel certain that they soon will have less fear of nervous complications and less nausea and vomiting during spinal anesthesia.

HAROLD P. McDONALD, M.D.      Atlanta, Ga.

### CONGENITAL DEFECTS

*To the Editor*—The interesting article regarding congenital defects appearing in *THE JOURNAL*, February 8, page 457, may cause some to assume that there were no previous data regarding the greater frequency of the occurrence of congenital defects among siblings. Maude Abbott has published some statistics regarding this increased frequency (in *Osler Modern Medicine*, ed. 3, Philadelphia, Lea & Febiger, 4:626) and I found the same in a small group (*The Causation and Prevention of Congenital Heart Disease, Arch Int Med* 48:721 [Nov.] 1931). Dr. Murphy has nevertheless presented some new statistics of value.

WILLIAM D. REID, M.D., Boston

### TOXICITY OF BORIC ACID

*To the Editor*—An American woman, aged 45 and weighing about 135 pounds (61 Kg.), was operated on for prolapse of the uterus and bladder and rectocele. At 9 p.m. the same day, 1 quart (1 liter) of saline solution was ordered given subcutaneously as she had lost some blood although she was in an entirely satisfactory condition. Almost two hours was consumed in taking the solution. When the nurse returned to the supply room she discovered that the patient had been given 1,000 cc. of 2 per cent boric acid solution, being a total of about 20 Gm. (310 grains). Nothing whatever occurred during the night that indicated she was suffering from ill effects caused by the solution.

Early the following morning examination of the urine for boric acid showed a very marked reaction, both by the sulfuric acid alcohol method and by the turmeric paper method. At 4 p.m. and at 8 p.m. the same day specimens were taken and they were markedly positive by both methods. On the second day, examinations of the urine made at 4 a.m., 8 a.m. and 4 p.m. were all positive but not so marked; specimens were concentrated, 75 per cent. On the third day, specimens taken at 4 a.m. and at 4 p.m. showed positive by the sulfuric acid alcohol method and negative by the turmeric paper method although the concentration was 75 per cent. On the fourth day, only a trace was shown by the sulfuric acid alcohol method and a negative reaction by the turmeric paper method. On the fifth day, specimens were negative by both methods.

Never at any time did the patient have more than a slight trace of albumin and a few casts in the urine. As far as could be observed, it did not affect her in any way. She had no symptoms of gastrointestinal irritation such as cramps, diarrhea or nausea except that she did vomit once, four hours

after the administration. As this was the first postoperative night she may have vomited from the anesthetic.

Dr. R. W. Webster in "Legal Medicine and Toxicology," page 405, reports that death has occurred in three and one-half hours but usually does not happen for a few days after the intake of these substances. He cites the following:

In the cases of McNally and Rust from three to six grams proved fatal to six infants while fifteen grams of boric acid was fatal to an adult and Birch reports the death of an infant who had consumed one and a half drachms (5.6 cc.) of sodium borate and boric acid in the form of honey of sodium borate and glycerin of borax while Potter describes a case of fatal borax poisoning in an adult from the taking of something over an ounce of borax in mistake for a saline laxative.

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### TYPHOID MENINGITIS

*To the Editor*—Can you give me some information relative to typhoid meningitis? In all available literature I find little reference to such a condition. Mrs. J. J. aged 30, mother of five children, was taken ill about September 15 with lassitude, pain in the back and legs and occasional bouts of fever. This persisted until I first saw her on September 27 at which time she was comatose. At no time had she complained of headache, visual disturbances, nausea or abdominal pain or diarrhea. I did a lumbar puncture September 28. The fluid was bloody and under decreased pressure. Laboratory reports for spinal fluid showed cloudiness and gram positive bacilli on a stained slide preparation, a colloidal gold curve of 0011110000. Pandey's reagent negative and ammonium sulfate reagent negative. A Widal test was positive on a blood specimen. A blood culture report has not been returned. For the last ten days (since September 28) the patient has been in coma except for periods of an hour or two on the second, fifth and eighth days. Neck rigidity appeared on the second day of coma. The Babinski, Chaddock and Oppenheim signs were noted as positive on the fourth day in coma. The abdomen was soft. No eye signs have been noted. Repeated lumbar punctures have shown decreased spinal fluid pressure. Using undiluted spinal fluid in the counting chamber 850 cells were estimated per cubic millimeter. A specimen obtained two days later (September 30) showed cells too numerous to count. The fluid was undiluted. A white blood count has been consistently around 8,900. The urine has contained a moderate amount of albumin but no casts, bacterial or blood cells. The temperature has ranged between 99 and 103 F. Three days ago the patient emerged from coma and has been rational since. Neck rigidity and pain in the back are still present. Two days ago she had diarrhea for a few hours which has not been noticed since. May one expect sequelae from the meningitis if such a diagnosis is correct? About how much more intestinal involvement may one expect? What are the incidence, prognosis and mortality of typhoid meningitis? What are common sources of infection other than drinking water and milk?

F. G. Slattery, M.D., Clare, Mich.

*ANSWER*—True typhoid meningitis is extremely rare. When it occurs, the spinal fluid is purulent and the typhoid bacillus may be isolated from it. It is practically certain that a patient with this condition will not survive. Sometimes in the course of an attack of typhoid, meningitis develops which is found to be due to other organisms than *Bacillus typhosus*. The meningococcus and also the tubercle bacillus have been reported as causative agents under such circumstances.

Serous meningitis in typhoid occurs more often than true typhoid meningitis. In the former, the condition is attributed to the action of the toxins of the typhoid bacilli. The organisms themselves are not found in the spinal fluid in this type of meningitis and a fatal termination to the disease is not necessarily imperative.

Meningitis is much more common in typhoid than any form of meningitis. Although symptoms suggestive of meningitis are present including some stiffness of the neck, there are no pathologic changes in the spinal fluid to substantiate the presence of meningitis.

Since the laboratory report on the spinal fluid of the patient states that the organism found was gram positive it would seem that the bacillus could not be the causative agent of typhoid which is gram negative. As the colloidal gold curve was normal and the globulin tests negative, one unacquainted with the patient might wonder whether the gram-positive

bacillus was not a contamination. If there is no true meningitis but merely meningism, the cell count reported might possibly be explained by the presence of blood in the spinal fluid.

It does not seem likely that the patient has typhoid meningitis; neither the laboratory report nor the improvement in her condition supports such a diagnosis. Several standard textbooks on medicine quote Cole, who collected thirteen cases of typhoid meningitis from the literature, all of these patients died.

If the patient's meningeal symptoms can be explained on the basis of meningism, no sequelae need be expected.

Two weeks is too early in the course of typhoid to make an estimate with regard to the extent of intestinal involvement that may be expected.

Sources of typhoid infection in addition to drinking water and milk may be the use of contaminated water for washing milk cans, uncooked vegetables or fruits. Uncooked vegetables, such as celery and radishes, may be contaminated if not thoroughly cleansed, contact with typhoid patients or typhoid carriers may result in transmission of the disease. Flies from outhouses may act in a mechanical way in carrying infection to uncooked foods, or to prepared foods after they are placed on the table for eating.

#### PAIN IN AMPUTATION STUMP IN PATIENT WITH MORPHINE ADDICTION

To the Editor—A man aged 58 has been suffering from severe burning pain in the stump of the right leg radiating up the course of the nerve trunks for six months since amputation at the junction of the upper and middle thirds of the tibia for gangrene of the foot, which originated from an injury to the right great toe. Because of chronic myocarditis the amputation was done under local anesthesia. There is much swelling of the stump and the thigh at times, but there are no other signs of vascular disturbance and this is relieved by hot applications and diathermy. The blood Wassermann test is negative. Repeated blood Wassermann and Kahn tests are negative. The spinal fluid Wassermann test is negative and the colloidal gold test is negative. The blood sugar is 154 mg per hundred cubic centimeters. Roentgen examination of the tibia and fibula shows evidence of a low grade periostitis. The urinalysis shows one plus albumin, few epithelial casts and granular casts and is otherwise negative. Red blood cells number 4,100,000, hemoglobin is 70 per cent, white blood cells number 8,900, polymorphonuclears 65 per cent, lymphocytes 32 per cent, eosinophils 1 per cent, monocytes 2 per cent. The basal metabolism rate is plus 5. It requires 1 or 2 grams (from 0.065 to 0.13 Gm.) of morphine daily to relieve the pain. The patient has gone for a period of six weeks without any opiates of any kind but experienced much pain. Examination of the stump reveals atrophy of the stump and retraction of the tissues. There are no palpable nodules (neuroma) present. Could it be possible that the nerves were not cut off high enough and that they have been caught up in the scar tissue? In view of the fact that the patient is unable to stand another amputation at the present would it be advisable to inject the nerves with alcohol and would this relieve the pain? What would be the best therapy in treating the patient to get him off the morphine since he has already become an addict if the injection of the nerves will relieve the pain? What would probably be the cause of the swelling of the stump and thigh since there is no other evidence of vascular disturbance. Anti-syphilitic treatment has been tried in the face of a negative Wassermann reaction but has not seemed to do any good. Any suggestions regarding the etiology and therapeutics in this case would be greatly appreciated. Please omit name.

M D Georgia

ANSWER—It is difficult to come to any definite conclusion in regard to the diagnosis in this case because changes that go with such diagnoses as thromboangiitis obliterans, other peripheral vasomotor disease or diabetes are not described. It is necessary to determine the presence of a pulse in the popliteal space of the right knee, and dorsalis pedis and popliteal pulse in the left lower extremity, as well as to make oscilometric studies of the vessels of the thigh and skin temperatures.

One of two conditions may be responsible for this picture. The evidence seems to point to a thromboangiitis obliterans of the vessels of the right lower extremity and that the patient continues to have symptoms of activity in the stump and thigh because he has rest pain in the stump as well as swelling of the stump and thigh. The periostitis is suggestive of some infection. The other condition is diabetes mellitus. The evidence here presented does not warrant such a diagnosis. The following regimen is suggested: absolute rest in bed, elevation of the stump and thigh, several injections (three or four) of typhoid and paratyphoid vaccine intravenously, with careful determinations of the skin temperature of the right stump and thigh as compared with the left leg and thigh, both before and after the injection. This will indicate the amount of vascular dilatation that takes place in the stump as well as relieving pain in the stump.

If pain persists, lumbar sympathectomy, chordotomy or injection of the peripheral sensory nerves with alcohol above the stump may be considered. The patient should take a gallon of Ringer's solution daily by means of a Rehfsuss tube.

The treatment of the morphine addiction should not be attempted until the treatment of the difficulty with the right stump and thigh has been completed. The following regimen is suggested: gradual daily reduction of the morphine, 12 to 15 units of insulin four times in twenty-four hours, sedation for a good night's rest with amytal or phenobarbital, large quantities of liquid and a highly caloric and palatable diet, and sugar solutions by mouth or vein for any symptoms of hypoglycemic shock that may appear following the insulin. This regimen should be carried on daily for from seven to ten days.

#### INTRAPLEURAL PRESSURE

To the Editor—1 In a healthy normal pleural cavity what is the greatest negative pressure attained (marked inspiration with the glottis closed)? 2 What is the greatest possible intrapleural pressure (marked expiration on coughing with the glottis closed)? 3 What is the ordinary variation in intrapleural pressure (ordinary inspiration and expiration with the glottis open)? Please omit name.

M D, New York

ANSWER—1 Forcible inspiration increases the negative pressure in the pleural cavity whether the glottis is open or closed. There is a greater negativity with the glottis open, in fact, so much that the water of the manometer would be aspirated into the chest cavity at times, or beyond a readable point on the water manometer, which is usually about 20 cm of water. The extent of negativity could reach as high as 30 mm of mercury, or about 30 + cm of water. With the glottis closed, however, there is little expansion of the lung, but there is a falling of the intrapulmonary pressure from rarefaction of air, and the intrapleural pressure falls with it, but to the extent only of a few millimeters of mercury or centimeters of water.

2 As stated, the usual water manometer on a pneumothorax machine measures about 20 cm of water pressure, and here again the positive pressure would be so great under the conditions stated, namely, a marked expiration on coughing with the glottis closed, that the water manometer would be exploded, but when measured in mercury it would be something like 30 mm or higher, depending on the force of the cough.

3 The ordinary variation of intrapleural pressure on ordinary inspiration and expiration with the glottis open, on inspiration, is from minus 6 cm of water to minus 10 cm of water, but the variation may be as low as minus 4 cm of water to minus 20 cm of water, at the height of inspiration. On expiration, the manometer would read from minus 4 to minus 8 cm of water, and sometimes may be as low as minus 2 to minus 12 cm of water.

The question reads for the reading of pressure in a healthy, normal pleural cavity, but the greatest clinical experiences in the reading of pressure within the pleural cavity are made under pathologic conditions, pulmonary tuberculosis in the main, in patients who come for treatment of their condition by means of artificial pneumothorax. Still, the pressure would not vary much from the normal, healthy pleural cavity.

#### TREATMENT OF CHLORINE GASSING

To the Editor—The Committee on Hazards from Use of Chemicals in Water Works Plants of the American Water Works Association is making an investigation of first aid treatments for victims of chlorine gassing with a view to making the following recommendations for treatments: (1) a simple method of first aid that can be used even in the smallest water works plant; (2) the most effective method of first aid regardless of how expensive the equipment may be.

H H GERSTEIN Sanitary Engineer Chicago

ANSWER—1 A simple method of first aid, which can be used even in the smallest water works plant.

First aid to patients gassed with chlorine may be applied in the absence of equipment if the following principles are considered: (a) Remove the patient from the toxic atmosphere promptly, (b) loosen all constricting clothing about the neck, (c) keep the patient absolutely quiet in a recumbent position, do not allow him to move, regardless of how free from symptoms he may appear a few minutes after gassing, (d) conserve body heat by keeping the patient warm with blankets, applying artificial heat in the form of hot water bottles, if available, (e) stimulants in the form of hot coffee and brandy are useful, (f) obtain the services of a physician as soon as possible.

These simple instructions should be posted about water purification plants in which liquid chlorine is used. The necessity for having a satisfactory gas mask available wherever chlorine cylinders are handled is obvious.

2 The most effective method of first aid, regardless of how expensive the equipment may be.

Wherever the hazard justifies, there should be a specially equipped safety or first aid room, and personnel trained in

caring for gas casualties should be available. Individuals gassed with chlorine should be carried to the first aid room immediately. In addition to the measures outlined in paragraph 1, facilities should be available for the administration of oxygen and venesection.

Oxygen should be administered in all cases. Do not wait for cyanosis to develop. The administration of oxygen will often prevent cyanosis and relieve the pain of deep inspiratory effort. Special oxygen masks or tents should be available for this purpose.

Venesection is an extremely valuable measure and should be performed early on all patients who have been exposed to heavy concentrations of chlorine. Its early use will often prevent the development of edema of the lungs and if used later it often relieves pulmonary edema and cardiac embarrassment. The early intravenous administration of dextrose or physiologic solution of sodium chloride given slowly in moderate amounts may be combined with venesection to combat shock and reduce the viscosity of the blood. Bleeding is contraindicated, however, in those cases which have reached the gray stage of anoxemia with pallor, collapse, and rapid, thready pulse.

Drugs are of secondary importance in the treatment of chlorine gas poisoning. Some authorities advise morphine for the pain and excitement that follow soon after injury, but it is agreed that morphine is contraindicated in the presence of pulmonary edema and respiratory embarrassment. Atropine and epinephrine are without effect and neither digitalis nor strychnine has been of much benefit. Brandy is useful as a stimulant. Caffeine in the form of hot coffee or hypodermic injection of caffeine with sodium benzoate is of value. Hypodermic injection of camphor in sterile oil is useful in serious cases.

The importance of early and efficient treatment of chlorine gassing should be constantly stressed, since the critical period is usually short, and most patients who live for twenty-four hours survive.

#### TREATMENT OF SYPHILIS

*To the Editor*—I am interested to learn when it would be safe to discharge a patient with syphilis as cured. The patient came under another physician's care in October 1933 with a chancre diagnosed by dark field and positive Wassermann reaction. The physician administered then twenty intravenous injections of neoarsphenamine and thirty intramuscular injections of sodium bismuth thioglycollate. The Wassermann reaction became negative. After a short rest of two weeks twelve more injections of neoarsphenamine and twenty of the bismuth compound were given. After another rest of one month twelve more injections of neoarsphenamine and twenty of the bismuth compound were given. A lumbar puncture was done and the cerebrospinal fluid examined. The cell count, protein, colloidal gold and Wassermann tests were all negative. To play doubly safe eight more injections of neoarsphenamine were given plus eight injections of sodium bismuth thioglycollate and twelve of insoluble bismuth the latter at weekly intervals. The patient is eager to take all the treatment to avoid any possibility of recurrence. His blood Wassermann reactions are repeatedly negative. All together he has been treated almost constantly for eighteen months. Is it safe now to dismiss the patient as cured? Kindly omit name. M D Nebraska

*ANSWER*—The best time for the treatment of syphilis is to begin immediately after an early diagnosis by dark field examination. At this early seronegative stage a permanent cure can be attained in a high percentage of infected individuals. This percentage decreases with delay in the treatment.

A cure requires at least eighteen months of continuous therapy with arsphenamine and compounds of bismuth or mercury. Twenty doses of arsphenamine and twenty doses of bismuth salicylate in from forty to fifty weeks are needed to assure permanent noninfectiousness. Thirty injections of the arsenical and from thirty to sixty injections of a bismuth compound in the first two years should be the therapeutic objective to prevent recurrence and late manifestations of syphilis. With such treatment, involvement of the aorta and central nervous system, which are the two most serious forms of late syphilis, can be prevented as well as other forms of latent syphilis. A "cure" will be attained of about 90 per cent of patients with a primary lesion. In latent syphilis the length of time necessary for a cure is more than eighteen months to two years.

This patient has received a total of fifty-two injections of neoarsphenamine and ninety injections of bismuth in eighteen months. The dosage per injection is not mentioned. With an average dosage this is sufficient to prevent late manifestations and it exceeds the quantities recommended by syphilologists at present. The Wassermann test and spinal puncture should be repeated every year, and a short course of treatment of ten doses of arsphenamine and ten of bismuth or mercury compounds each year for three years would be advisable.

#### BASS JOHNS BLOOD COUNTING CHAMBER

*To the Editor*—Please send me directions for the use of a Bass Johns blood counting chamber. P E PARKER M D Johnson City Tenn

*ANSWER*—The Bass Johns blood counting chamber is described in the book on Laboratory Diagnosis by Bass and Johns, Rebman Company, 1917.

The counting chamber consists of a heavy object slide on which a small oblong counting plate is cemented. The Bass ruling in the middle of the counting plate consists of a square of 2 mm size. This is divided into ten 0.2 by 2 mm rectangles for counting leukocytes. For counting erythrocytes there are superimposed on the ruled space at each corner and in the center five 0.2 mm squares, each further divided into sixteen 0.05 mm squares. The cubic contents of the entire ruled space 0.1 mm deep, is 0.4 cu mm. The total cubic contents of the five large squares is 0.02 cu mm.

Pipets for dilution are used as with any other counting chamber. All the leukocytes in the ten rectangles are counted. Multiply by 250 to get the number per cubic millimeter when a dilution of 1 to 100 has been used. If a 1 to 20 dilution is used, multiply by 50. In counting the erythrocytes, there are five large squares each ruled into sixteen small squares. The red cells in all five large squares are counted. The total number in the five large squares multiplied by 5000 equals the number of cells per cubic millimeter when a dilution of 1 to 100 is used.

#### PYODERMIA AND IRRITANT DERMATITIS

*To the Editor*—There is no dermatologist near and I am sending a patient's picture. Lesions began about seven weeks ago as small pimples and drained pus. I did not see him until about three weeks ago. Mercurochrome was just put on the lesions. When I saw the patient the skin was scablike and the nodules ran pus. He had some pain. Wet dressings were applied and the skin came off the lesions cleared up with the exception of nodules as in the picture. Today he has pain and they are coming out again. The patient has had one application of x-rays but I think there is too much inflammation to continue. I could not get a good potassium hydroxide mycelium test. The lesions are limited to the dorsum of the forearm from the wrist to the elbow and do not go any further. Bullae, erythema multiforme and blastomycosis or some fungus may be in order. Is it blastomycosis? I am using potassium iodide and sulfur dioxide pastes. Can you tell me what this is? M D Colorado

*ANSWER*—From the description and photograph this man apparently has a pyoderma that is superimposed on an underlying irritant dermatitis. The eruption is sharply defined over the dorsum of the hands and at the elbows and suggests a reaction to some external irritant which might be a chemical household or occupational contact. The possibility of a plant irritant from contact with foliage in the man's environment has to be considered.

The clinical picture as shown in the photograph does not simulate blastomycosis. Erythema multiforme might be an underlying condition on which the pyoderma is superimposed. In erythema multiforme, however, other lesions would be present about the trunk, face and possibly the anogenital area.

The ingestion of drugs should be ruled out and the surface infection treated with mild antiseptic wet dressings such as aluminum subacetate solution, 1:16 or 1:1000 mercurinol or 1:5000 metaphen solution. After the acute dermatitis has subsided the use of 2 per cent ammoniated mercury ointment, gradually increasing to 5 per cent, can be used. Local infected areas may be painted with 3 per cent aqueous gentian violet solution. The patient's general condition should be built up with hematinics and vitamin A and B by mouth.

#### DIAGNOSIS OF DEATH FROM DROWNING

*To the Editor*—A girl aged 19 years was found floating in a creek near here. She left her home at 9 a m and was found about 5 p m the same day. Rigor mortis had set in. Would the fact that she was floating preclude the possibility of her having drowned as the cause of death? Could a person be drowned and immediately say within an hour rise to the surface and continue to float until found? What factors determine how soon a drowned person rises to the surface? I will appreciate your answering this as promptly as you possibly can. Please omit name if published. M D Texas

*ANSWER*—The fact that the body was floating when found would not exclude death from drowning. The specific gravity of the human body immediately and soon after death would be practically the same whether death has resulted from drowning or from some other cause. Drowning per se can have no special influence on the floatage of a dead body.

Generally speaking the body of a drowned person would not rise to the surface within say one hour after drowning and continue to float for some hours afterward but such a possibility under certain circumstances cannot be denied. In the case in

question was the body buoyed up by clothing? How deep was the water and was the depth uniform and without any shallow places? Was there a strong current? Were there any stakes or other objects in the water that might support the body? Occasionally dead bodies of women have been found floating a few inches under the surface while some of the clothes rested on the surface of the water.

Obviously a variety of factors come into play in the rising to the surface of a human body after submersion in water: the depth, specific gravity, motion of the water, the amount of fat on the body and its clothing as well as internal conditions that may affect the rate of decomposition climatic and seasonal conditions. It is said that in warm climates and in summer, bodies may rise on the first day, but this is quite exceptional.

#### GYNecomastia

*To the Editor*—A man aged 47 a lathe worker in a copper utensil manufacturing plant for the past year has noticed a gradual increase in the size of the right breast until at present it is nearly twice as large as the left breast. There are no nodules no puckering of the skin over the breast and no enlargement of glands or retraction of the nipple, which appears normal. The substance of the breast feels normal transillumination is negative. There is no pain or distress in or around the breast. It seems normal in every respect except for the increase in size. In the man's work the stick that holds the cutting tool of the lathe presses against the right side of the chest and has caused from time to time soreness and some localized edema in the lower part of this breast which disappears after a short time. There is no edema at present. I should like to know whether the local irritation could be the cause of this condition or of any other possible causes.

L. S. McMILLAN M.D. Rome N. Y.

*ANSWER*—The patient is probably suffering from unilateral gynecomastia. Gynecomastia is a disorder of the male breast in which the gland tends to assume the size, shape and sometimes function of the female breast. The condition may be either unilateral or bilateral. The enlargement is sometimes accompanied by secretion. Two distinct types are recognized: (1) cases associated with an abnormal sexual function and sometimes demonstrable testicular defects, and (2) cases in which no abnormality of the sexual function is demonstrable. Examples of gynecomastia in which the enlargement of the breast appear to bear an etiologic relationship to a previous trauma are recorded in the literature, but the relationship between the enlargement of the breast and the trauma cannot be stated with absolute certainty. The possibility of trauma acting as the contributing cause must be entertained. At the same time it should be stressed that the condition usually occurs in the absence of demonstrable trauma.

#### TIME OF DAY FOR HEAVY MEAL

*To the Editor*—Given the following circumstances would you kindly inform me whether the heavier meal should be served at dinner or supper: 1 Breakfast at 7:15 a.m. work from 8 to 12 noon. 2 Dinner at 12:15 p.m. work from 1 p.m. to 4 p.m. 3 Supper at 5:15 p.m. rest until lights out at 9:30 p.m.

M.D. Montana

*ANSWER*—The eating of the larger meal in the evening or at noon is largely a matter of individual preference, habit and convenience. Many men find it inadvisable to eat the large meal at noon because this makes them sleepy for two or three hours afterward. The lighter lunch the more wide awake they are for the afternoon's work. A physician will sometimes advise a patient to eat a light meal in the evening because he may then get a better night's rest. This is particularly true for the patient with a diseased gallbladder who tends to be distressed and bloated after a large meal.

#### EFFECTS OF OIL OF PEPPERMINT

*To the Editor*—Does the administration of natural oil of peppermint in doses of from 2 to 5 minims (0.1 to 0.3 cc.) three times a day over several months reduce or alter bile production? Would the synthetic oil be more deleterious than the natural? In two cases in which this dosage was given in connection with the use of dextrose by mouth in large doses the phenomenon of clay colored stools was noted. I shall much appreciate your comments.

H. A. GREENWOOD M.D. Maracaibo Venezuela

*ANSWER*—Oil of peppermint has been shown to have a tendency to increase the secretion of bile, but it would have to be used in larger dosage to have any marked effect. If by synthetic oil of peppermint is meant a peppermint oil that has been enriched by the addition of menthol so as to come up to the official requirements, it is obvious that the effect of this oil will be the same as that of the "natural" product. If the dose of dextrose is very large, it might have some effect in making the stools lighter colored.

#### TYPHOID TRANSMISSION BY RECTUM

*To the Editor*—Is there any known reference to typhoid transmission by rectum? As in an epidemic in an institution is it possible to transmit the disease by the use of improperly or unsterilized rectal tubes? Please omit name.

M.D. Pennsylvania

*ANSWER*—There does not seem to be any record of transmission of typhoid by way of the rectum through the use of tubes contaminated with typhoid bacilli. The possibility that typhoid can be transmitted in that way, of course, cannot be denied.

#### POSSIBLE REACTION FROM HAIR WASHES

*To the Editor*—Please give me your opinion as to what reaction might result both local and constitutional from the following procedure: A solution of 12 Gm. of sodium sulfite and 8 ounces (236 cc.) of water is applied to the hair with a piece of cotton and left on from six to twelve hours. The hair is then washed with soap and water, rinsed with plain water and then rinsed with a solution of tartaric acid U.S.P. 12 Gm. to a gallon of water. The tartaric acid solution is then immediately rinsed off with plain water. Please omit name.

M.D. California

*ANSWER*—The solution of tartaric acid is obviously used to remove the last traces of sulfurous acid odor from the hair. Neither local nor constitutional reaction is likely to follow such treatment unless the patient's skin is hypersensitive.

#### ANTI-TYPHOID INOCULATION

*To the Editor*—Would you kindly tell me the latest method of typhoid vaccination? I have always used three weekly increasing doses subcutaneously. I understand there is now an intracutaneous method similar to the one used in diphtheria but I have no information whether it is efficient. What is your opinion? Please omit name.

M.D. Minnesota

*ANSWER*—No new method of preventive antityphoid inoculation has been introduced into practice.

#### TRYPARSAMIDE DERMATITIS

*To the Editor*—In *Queries and Minor Notes* (THE JOURNAL February 29, p. 726) in answer to a question on skin reactions with arsenicals the statement is made that tryparsamide is the only one of the commonly used organic arsenicals that does not cause skin eruption. In the *American Journal of Syphilis and Dermatology* (18:308 [July] 1934) a report of a case of tryparsamide dermatitis with a survey of the literature was presented. The patient developed a classic exfoliative dermatitis with redness and edema of the skin, signs of toxicity, fever, universal scaling and loss of hair after three injections of tryparsamide. A. L. Skoog (Tryparsamide Therapy in Neurosyphilis, *J. Missouri M. A.* 22:387 [Oct.] 1925) reported that dermatitis in a mild form was seen but once in a summary of a thousand injections of tryparsamide in a series of cases. J. R. Phelps (Reactions Incidental to the Administration of 191,778 Doses of Neoarsphenamine and Other Arsenical Compounds in the U.S. Navy, *U.S. Nav. M. Bull.* 27:205 [Jan.] 1929) observed one mild skin complication in a study of 4,488 doses of tryparsamide. Other scattered instances were noted in the literature. Although the frequency of skin reactions due to the use of tryparsamide is very small nevertheless this complication must be borne in mind.

LOUIS J. BRAGMAN M.D., Binghamton N. Y.

#### ALLERGY TO TRYPARSAMIDE

*To the Editor*—In THE JOURNAL February 15, page 564, I observed a notation stating that there are no records of allergic reactions following the use of tryparsamide. While the question of just what constitutes an allergic reaction may be a moot one and drug idiosyncrasy does not fulfil by far the requirements of true allergy, severe reactions of this type have been reported. In April 1934 (*Brit. J. Ven. Dis.*) I briefly reported a case of severe nitritoid reactions to tryparsamide. I have recently seen in my private practice a similar case in which definite urticarial reactions following tryparsamide also developed. The patient had previously been similarly intolerant to neoarsphenamine. The history of the reactions was interesting. After the eighth injection of tryparsamide he was slightly nauseated. After the thirteenth slight flushing of the face and a few wheals on the neck and forearms were noticed. These were controlled by atropine until the eighteenth injection when the Bezredka technic was instituted. Despite all precautions however the urticaria gradually became more severe and became generalized at the thirty-first injection. Following this and two subsequent injections it was accompanied by nitritoid reactions of increasing severity but controlled by epinephrine. The tryparsamide was discontinued after the thirty-third injection because of the intensity of the reaction and at the present time the patient who has asymptomatic dementia paralytica is receiving fever therapy.

FRANK E. CORNIA M.D. Montreal

#### DERMATITIS DUE TO RUBBER GLOVES

*To the Editor*—I have read with considerable interest the query in the February 29 issue, page 730. What can be done for dermatitis produced by the use of rubber gloves? Being bothered with a similar condition for the past year I began experimenting and have found that bathing and steeping the hands in a saturated solution of boric acid just before and following the use of the gloves is very helpful. I have made at a point also to dust the hands well with talcum powder before putting on the gloves.

T. C. BAILLY M.D. San Francisco

### New York June Examination

Mr Herbert J Hamilton, chief Professional Examinations Bureau reports the written examination held in Albany Buffalo, New York and Syracuse June 24-27, 1935. The examination covered 9 subjects. An average of 75 per cent was required to pass. Six hundred and fifty two candidates were examined 541 of whom passed and 111 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Arkansas School of Medicine	(1932)		1
Yale University School of Medicine	(1935)		1
George Washington Univ School of Med	(1934-5)	(1935-5)	10

## Book Notices

**Electroprexia in General Paralysis** By Leland E. Hinsie M.D. Research Associate in Psychiatry New York State Psychiatric Institute and Hospital and Joseph R. Blalock M.D. Senior Physician (Psychiatrist) New York State Psychiatric Institute and Hospital With a preface by Clarence O. Cheney M.D. Cloth Price \$1.25 Pp 90 with 3 illustrations Utica New York State Hospitals Press 1934

This monograph describes the experiences of investigators at the New York State Psychiatric Institute and Hospital in the application of artificially induced fever to dementia paralytica. These workers utilized the short radio waves produced by an ultra high frequency oscillator to reproduce as closely as possible the temperature curves produced by inoculated malaria. Approximately half of the monograph is devoted to a critical analysis of the experiences of other workers in this field. There is an excellent review of the literature dealing with physiologic responses to artificially induced fever.

All of the 105 patients subjected by Hinsie and Blalock to artificial fever therapy exhibited the clinical and laboratory signs of dementia paralytica of the adult type. None had received previously any of the antisiphilitic forms of treatment that are known to be beneficial in dementia paralytica. All were subjected essentially to the same technic from the standpoint of high frequency pyrotherapy. All were selected on the basis of suitability for fever therapy. These requirements were essentially the same as those applied to candidates for malaria therapy.

For purposes of comparison the patients were divided into three groups. The first group consisted of fifty-one patients who were treated by thermotherapy only. The second group consisted of twenty-seven patients who were treated with an equivalent amount of thermotherapy and who received, six months later, either tryparsamide and mercury therapy or a course of inoculated malaria. The third group of twenty-seven patients received a similar course of pyrotherapy, followed immediately by one or more courses of tryparsamide and mercuric salicylate in oil. A comparison of the results attained in the treatment of the group of patients who received thermotherapy alone, with those who received thermotherapy followed six months later by some other form of therapy, revealed that the addition of chemotherapy or malaria therapy after the interval of six months was of little or no benefit. In the third group of patients, treated by thermotherapy followed directly by chemotherapy, the clinical results were distinctly better. The remission rate of the patients of the first two groups one year after treatment was 21.7 per cent while the remission rate one year after the termination of treatment in the third group was 37 per cent.

This monograph will be of particular interest to the neuro-psychiatrist, the syphilologist and those who are engaged in investigations in artificial fever therapy.

**The Phenomena of Life: A Radio Electric Interpretation** By George Crile. Edited by Amy Rowland. Cloth Price \$3.50 Pp 379 with 113 illustrations. New York: W. W. Norton & Company Inc. 1936.

Into this book the author has put most of the biologic investigations and speculations that have interested him over a third of a century. It is interesting reading coming from a busy surgeon but not easy reading. Some doctors take to golf others to bridge while Dr Crile seeks his stimulation and recreation in the profundities of biology. The radio electric interpretation of living processes may not appear very convincing to the biologists, but the tale of Dr Crile's quest "Why did William Landman die?" is a charming one and human even in its incompatibilities and contradictions. The basal metabolic rate does not drop 50 per cent during sleep (p 163). The

human infant has no natural weapons for attack yet he seems to experience both fear and anger (p 187). It may worry the thoughtful to find worry defined as "interrupted stimulation" (p 189). Others may be curious to know how this noted surgeon has "tested in the crucible of the clinic" (p 18) the theory that the armadillo, the snake, the porcupine and the skunk "show little or no fear" and "have simple adrenal-sympathetic complexes" (p 187). Many readers will fail to see that Dr Crile's radio-electric interpretation of life is in any way strengthened by the assertion that "no amount of trauma, no amount of physical injury in an area where the sensory nerves are blocked by local, regional or spinal anesthesia can cause excitation, depression or death" (p 357) for, as a generalization this seems not proved. The author's service to practical surgery is greater than his contributions to the philosophy of biology. But why may not a doctor try his wings in the stratosphere, along with physicists and astronomers? At least to date he broad casts on "autosynthetic cells" and "radiogens" (built on the plan of the solar system), not on free will and God.

**The Principles and Practice of X Ray Therapy** By Ffrangcon Roberts M.A. M.D. M.R.C.I. Physician in charge of the Dauty X Ray Clinic Addenbrooke's Hospital Cambridge. Cloth Price 10s 6d Pp 214 with 115 illustrations. London: H. K. Lewis & Co. Ltd. 1936.

This book presents facts relative to x-rays and their therapeutic applications in a simple and concise manner from which an excellent basis and rational conception for the practice of roentgen therapy may be acquired. Fundamental principles especially are described in an easily comprehensible manner and correlated with practical application. The physical aspects discussed include the nature and source of x-rays, means of production, passage through matter, measure of quantity and quality, surface and depth doses and the methods of application to obtain desired results. Factors explaining the rationale of various technic such as massive, fractional saturation and protracted fractional dose methods are given consideration. Chapters are devoted to the biologic action of x-rays on normal tissues and to the general principles in connection with malignant disease. The quality of radiation as related to therapeutic effect, stimulating doses, radioimmunization, accessory methods of increasing the coefficient of sensitiveness, and preoperative and postoperative irradiation are all discussed briefly. That part of the book covering the practical therapy of particular conditions apparently is intended to give the reader merely a general perspective of the conditions amenable to roentgen therapy. In it, malignant disease in the commoner situations, lymphogranulomas, diseases of the blood-forming organs, hyperthyroidism, nonmalignant diseases in women, diseases of the skin and miscellaneous diseases are given consideration more or less sketchily. Details presented in connection with some of the conditions appear to be out of proportion to those accorded to others. Although the book cannot classify as an exhaustive treatise on the subject it is intended to cover, it forms a valuable reference work on present day practice. With out overenthusiasm it shows what may reasonably be expected from roentgen therapy based on theories grounded on established facts.

**Dyke's Automobile and Gasoline Engine Encyclopedia: The Elementary Principles, Construction, Operation and Repair of Automobiles, Gasoline Engines and Automobile Electric Systems, Including Trucks, Tractors, Motorcoaches and Motorcycles** By V. L. Dyke. Seventeenth edition (Silver Anniversary Edition). Cloth Price \$6 Pp 1311 with illustrations. Chicago: Goodheart-Willcox Company Inc. 1935.

This is a practical book treating on the principles, construction, operation, repairing troubles and remedies of automobiles and gas engines. It is compiled with three general classes of readers in mind—students, repairmen and car owners. The fact that the first edition was published in 1910 and that there have been sixteen editions since then is proof enough that it has served as a reliable reference book for automotive information. The thirteenth edition was completely rewritten, subsequent editions have been revisions of the thirteenth. It has two indexes and the addenda are in three sections. The main body of the book deals with the fundamental principles of the motor car while the addenda cover the modern improvements of various cars. Thumbing through the index and looking up various items listed one finds that almost any subject is considered, for example, there are explanations of ignition systems.

and how to repair them, diagrams of the starter systems, descriptions of superchargers and how they work—all of which and much more is explained in nontechnical language. Quackery is not prevalent in automotive practice, but it appears to creep in in at least one instance. Doubtless every physician has been impressed by the demonstration of the sidewalk salesman selling so-called spark intensifiers. He shows that the spark plug can be made to work even when completely carbonized and filled with oil. In this book there is an explanation why these devices are worthless and a hindrance to perfect performance of the car. The author makes no attempt to evaluate the advertised important features of each make of car which the salesmen use in their sales talks. Any physician who is inquisitive as to the operation of his or any make of car should find this volume a valuable addition to his library.

*Atlas of Human Anatomy with Explanatory Text.* By Jesse Feiring Williams. M.D. Columbia University. Cloth. Price \$2. Pp. 64 with colored illustrations by Franz Frohse, Max Brodel and Leon Schlossberg. New York: Barnes & Noble Inc. 1935.

The first part of this small book is a brief general discussion of the anatomy of the human body by systems. This part evidently was prepared especially for the instruction of laymen and it is illustrated with drawings. The second part of the book comprises about twenty-seven pages of colored anatomic charts, some of which are miniatures of the well known life-size charts prepared by Franz Frohse of Berlin and formerly published in America by A. J. Nyström & Co. of Chicago. In addition the book contains colored charts of the throat, heart, neck and genito-urinary organs made by Prof. Max Brodel of Johns Hopkins University School of Medicine. There are also several colored charts of the brain and skull and of the alimentary tract drawn by Mr. Schlossberg in cooperation with Professor Brodel, by whom the entire series has been carefully revised and corrected where necessary. These charts have been edited and grouped so that related subjects appear close to one another. They are exceptionally clear and well drawn and it is simple to locate on the page the numerous anatomic parts named and indicated by numbers and dotted lines. This handy volume should be interesting to laymen, and also useful to physicians when they have occasion to explain the anatomy of the human body.

*Voprosy obshchey i chastnoy rentgenologii. Sbornik rabot kafedry rentgenologii gosudarstvennogo instituta dlya usovvershenstvovaniya vrachev i Leningrada. Pod redaktsiei Prof. S. A. Reynberga. [Problems of General and Special Roentgenology. Collected Works of Department of Roentgenology of Leningrad State Institute for Training of Physicians.]* Cloth. Pp. 285 with illustrations. Moscow and Leningrad: Izdatel'stvo Akademii nauk U. S. S. R. 1935.

This is the first published volume from this department of roentgenology which was founded three years ago. The contributions consist of investigations in the fields of cardiology, diseases of the gastro-intestinal tract, the central nervous system and the pathology of bones and joints, with special chapters dealing with the use of x-rays in agriculture, the biologic effects of ultrashort waves and the organization of roentgenologic service on trains. The scope and scientific quality of the material presented suggest that roentgenology in the Soviet Union while not technically as far advanced as it is in the United States is making progress.

*The Modern Treatment of Burns and Scalds.* By Philip H. Mitchiner. M.D. M.S. F.R.C.S. Hon. Surgeon to H. M. The King. Cloth. Price \$2. Pp. 64 with 12 illustrations. Baltimore: William Wood & Company, 1935.

This monograph on the treatment of burns is essentially a presentation of the technical details of the author's modification of the tannic acid treatment in the early stages of burns and scalds. The discussion of the causes leading to death in burns and scalds is brief. The author's statement that the absorption of histamine bodies from the damaged tissues is generally accepted as the cause of collapse in the early stages of burns is not entirely in accord with the literature on this subject. The same may be said of his statement that acid burns should be treated with alkaline solutions and that alkali burns should be treated with acid solutions. Such important points as restoration of fluid loss, the transfusion of blood in extensively burned patients who are apparently in good condition, and the restoration of blood chlorides are sketchily dealt with. The author's discussion of the importance of using the proper solution of

tannic acid is to be commended, although it is regrettable that he does not extend this investigation beyond the determination of the concentration of tannic acid. The effect of the pH of the solution is ignored. The principal criticism of the book is the overemphasis on a single method of treating the wound. This is especially apparent in the table of statistics on the mortality of burns and scalds in St. Thomas's Hospital from 1894 to 1932, in which the figures are presented in such a manner as to lead one to believe that a reduction of mortality from 30.8 per cent to 2.4 per cent is to be ascribed entirely to the use of a 2.5 per cent tannic acid solution. These figures are not in accord with some which have been published by other clinicians within recent years and they emphasize again the shortcomings of physicians in the application of statistical methods to clinical problems. The principal value of the book is that it directs attention to an extremely important and, until recently, sadly neglected field of medical and surgical practice.

*Anomaliї rosta i razvitiya. [By] Dotsent B. I. Morgulis. S predislavleniem Prof. V. M. Kogan. Yasnogo. Acta Endocrinologica Ukrainica. Part 5. [Anomalies of Growth and Development.]* Paper. Price 4 rubles 50 kopecks. Pp. 120 with 75 illustrations. Kharkov: Izdanie vseukrainskogo Instituta endokrinologii i organoterapii. 1934.

The monograph is an attempt to present systematically various anomalies of growth and development. The etiology and pathogenesis are discussed and prophylaxis and therapy are suggested. While there is nothing new or original about the observations presented the value of the monograph lies in a rather large personal material of the author.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Pharmacists Liability for Sale of Poisons to Minor—** Martha McGhee, a minor between the ages of 15 and 16 years, in a mood of despondency, determined to commit suicide. After unsuccessfully attempting to purchase poison at three drug stores she succeeded in buying a quantity of bichloride of mercury tablets and a bottle of tincture of iodine from the defendant drug store. She swallowed eight or nine bichloride of mercury tablets and drank the bottle of iodine. Death was averted by prompt medical attention, but the girl was severely injured by the poison. She and her father instituted separate suits against the defendant drug store to recover damages, the cases were tried together, the trial court gave judgments for the plaintiffs and the defendant appealed to the court of appeals of Tennessee, eastern section.

The declarations in each case alleged as causes of action (1) that the employee of the defendant drug store knew, or by the exercise of reasonable care should have known, that the girl was in a state of temporary insanity, that she was likely to take the poison, and that in making the sale the employee thus was directly responsible for the girl becoming poisoned and for the resulting injuries, and (2) that the defendant was negligent through its employee, in selling poison to a minor under 16 years of age, not on the written order of some responsible adult person, a Tennessee statute forbidding such a sale. In thus violating the statute, said the appellate court, the defendant was guilty of negligence per se and if that negligence was the proximate cause of the injuries suffered, the defendant was liable. In the case of *Meyer v. King*, 72 Miss. 1, 16 So. 245, 35 L. R. A. 474, relied on by the court in the present case a mother brought suit against a druggist to recover damages for the death of her son which had resulted from drinking chloroform sold to him by the druggist in violation of a Mississippi statute. Finding that the son had reached the age of discretion and that he knowingly and voluntarily drank the chloroform the court in that case held that his act in drinking the chloroform and not the act of the druggist in selling it to him was the proximate cause of his death. So, in the present case, the court was of the opinion that the act of the girl in swallowing the bichloride of mercury tablets and in drinking the iodine was the proximate cause of her injuries, unless her

reason and memory were, at the time, so far obscured that she did not know and understand what she was doing. The evidence was clear, in the opinion of the appellate court, that the girl voluntarily formed a purpose to end her life by means of poison, that she sought and procured the poison which she thought necessary to accomplish that purpose, and then promptly swallowed the poison with full knowledge of what she was doing and in the belief that it would destroy her life. The record contained no testimony of medical expert witnesses with respect to the mental condition of the girl, and the court could find nothing in the record to afford a reasonable basis for an inference that she was insane or mentally incompetent to the extent that she did not know and comprehend the full import and consequences of what she was doing at the time in question. The appellate court, therefore, reversed the judgments against the defendant and dismissed the suits. *Certiorari* was denied by the Supreme Court of Tennessee—*Eckard's Inc. v McGhee* (Tenn.) 86 S W (2d) 570

**Hospitals Liability for Injury to Pay Patient in County Hospital**—Pursuant to statutory authority Twin Falls County, Idaho, erected and operated a county hospital. Pay patients were admitted and the county derived a profit from the operation of the hospital. Following an appendectomy on the plaintiff a pay patient her physician prescribed an injection of a normal saline solution to be administered by a special nurse. An employee of the hospital gave to the nurse a container containing a liquid similar in appearance to a normal saline solution but which actually contained boric acid. The nurse injected the boric acid solution and severe sloughing resulted. And while in the hospital the plaintiff contracted typhoid fever, which she attributed to her diminished powers of resistance caused by the injection of the boric acid. Thereafter the plaintiff sued the county to recover damages for her injuries. The trial court dismissed the suit and the plaintiff appealed to the Supreme Court of Idaho.

The Idaho statute providing for the erection of county hospitals, said the Supreme Court, merely provides that county commissioners shall have power to erect, or to lease equip and operate a county hospital. The statute imposed no obligation on counties to erect hospitals. It was permissive in character only. Whether or not the county was liable for the negligence of hospital employees in the present case, the court said depended on whether in operating the hospital the county was engaged in a governmental function. A duty is imposed on the county to take care of the indigent sick and otherwise dependent poor. The county might discharge that duty directly or by contract. Having built the hospital to discharge its public and governmental duty, it had the power to utilize any excess facilities it possessed for serving pay patients. In serving pay patients, however, the county was not engaged in the discharge of its public and governmental duty, it was engaged in a private and proprietary business for pay. Its relation to pay patients is the same as the relation of any privately owned hospital toward a patient. The county urged that if it should be held liable for injuries to pay patients it might be embarrassed financially by being required to pay heavy damages. That might prove true, said the Supreme Court, but the remedy lies with the county. It may either carry insurance to protect it against such risks or refuse to accept pay patients.

The county further contended that the hospital was a charitable institution and that the county was not for that reason liable to a pay patient. In answering this contention the Supreme Court of Idaho referred with approval to the case of *Tucker v Mobile Infirmary Association* 191 Ala., 572, 68 So 4 in which it was held that a pay patient in a hospital conducted without profit could recover damages for an injury caused by the negligence of an attending nurse, and to the case of *Mullner v Evangelischer Diakonissenverein of Minnesota Dist of German Evangelical Synod of North America* 144 Minn 392, 175 N W 699, in which a similar principle was applied.

The court concluded, therefore, that in supplying hospital care to the plaintiff the county was acting in a proprietary and corporate capacity and that it was liable for the negligence of the hospital employees. The judgment of the trial court dismissing the plaintiff's suit was reversed—*Henderson v Twin Falls County* (Idaho) 50 P (2d) 597

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

- Heart Block Following X-Ray Treatment for Thyrotoxicosis. D N Kremer and L B Laplace Philadelphia—p 227

**The Heart in Emphysema**—Kountz and his associates confine their study to true emphysema such as follows asthma and other obstructive lesions of the bronchi. From their observations it appears that 1 The heart is affected in the majority of patients with emphysema 2 The lesion cardiac hypertrophy with dilatation of the right ventricle when advanced may produce symptoms but probably has no clinical reflection in its earlier stages 3 The cause of the left ventricular hypertrophy remains as yet undetermined 4 There is experimental evidence which indicates that the right ventricular dilatation and hypertrophy occur chiefly in the earlier stage of emphysema when the lungs are in the process of distention, rather than later as generally believed

**Electrocardiograms and Phases of Cardiac Systole in Pellagra**—In Feil's study of thirty-eight cases of moderate to severe pellagra, electrocardiographic abnormalities in the ventricular complex occurred in 50 per cent. In fourteen of these nineteen cases there was no complication that might alter the electrocardiogram (36.8 per cent). The chief abnormalities were inversion of T waves in leads 1 or 2 or both Pardee type of ST and large T waves. Lead 4 was abnormal in twelve of thirty-three cases in which it was recorded (36.4 per cent). Lead 4 was abnormal in four cases with normal leads 1 2 and 3. The QT interval and mechanical systole were prolonged in some cases. These observations suggest that the heart is affected physiologically in pellagra. Twelve hearts (one of which was studied electrocardiographically and dynamically) examined pathologically showed no gross or microscopic abnormality. Roentgenographic changes were lacking in the cases studied.

**Influence of Posture on Partial Heart Block**—Alexander and Bauerlein observed a patient with partial heart block, presumably of organic nature who had a ventricular rate much faster in the upright position than when recumbent. It appears

that this discrepancy is due to vagus effect. Under atropine medication the block (other than a prolonged PR interval) and its attendant symptoms disappeared.

**Fibrosis of Placenta**—Montgomery reviewed his cases of placental sections studied the histories of the corresponding patients and endeavored to determine what effect the so-called lesion of fibrosis has on the weight of the new-born, what effect it has on the occurrence of stillbirth, and what conditions gave rise to a diagnosis of fibrosis if such is not a pathologic entity. Among the records of 700 placentas examined grossly and microscopically, he found 101 in which mention was made of increase in density of the connective tissue of the villous stroma and fifty-four in which the deposit of fibrous tissue round the fetal vessels of the placenta appeared heavier than normal. A review of the cases in which diagnoses of 'diffuse fibrosis of placental villi' and 'perivascular fibrosis of placental vessels' were made reveals that the fetuses born at or near term were of average weight and that the rate of stillbirth was no higher than could be accounted for by other specific causes. A reconsideration of the histologic sections leads the author to doubt that either one of the lesions described is a pathologic entity. He sets forth several circumstances that confer on the placenta a false appearance of fibrosis: normal variation in architecture between different placentas; variation between individual sections of the same placenta; collapse of the vascular tree of the placenta and states of immaturity of the organ. Particular objection is raised to the practice of loosely applying the term 'fibrosis' to indurated areas of the afterbirth. These areas are found on microscopic examination to be zones of necrosis or of intervillous thrombosis. Attention is directed to lesions of the syphilitic placenta: hyperplasia of the connective tissue stroma and vessel wall alterations. The author finds no disturbances here that can be directly attributed to syphilis as a disease. He interprets these lesions as evidences of arrest of development of the placenta due to arrest of fetal vitality. The same appearances were found in stillbirths of the same period due to other causes.

**Intraspinal Alcohol Injections and Sympathectomy for Pain Associated with Carcinoma of Cervix**—In an attempt to analyze their results with both sympathectomy and alcohol injections for the relief of pain in carcinoma of the cervix, Greenhill and Schmitz selected their first forty sympathectomies and forty alcohol injections. The eighty women had group 3 or group 4 carcinoma of the cervix when they first came under observation. The comparison demonstrates conclusively that better results are obtained by means of intraspinal injections

of alcohol. In addition to the greater incidence of relief obtained by means of the alcohol injections, this procedure is far simpler than sympathectomy. Some women will not be benefited by intraspinal injections of alcohol. Practically all pain associated with carcinoma of the cervix can be relieved except that which is due to involvement of the upper part of the urinary tract in the form of hydro-ureter and hydronephrosis. This complication produces not only pain high up in the renal region but also severe discomfort in the parametrium on the affected side. The authors have not been able to stop this pain by intraspinal injections in the lumbar region. Whether injections made higher up (in the thoracic region) can do this they are not prepared to say, because they have not tried this as yet. Pain in the pelvis in cases of cervical carcinoma due to pyometra can readily be relieved by dilation of the cervix to permit drainage of the uterine cavity. Pain due to invasion of the bladder with or without fistula formation can be relieved by either pelvic sympathectomy or alcohol injection. However, obstruction or invasion of the ureter with hydro-ureter and hydronephrosis cannot be relieved except by nephrectomy. Pain due to extension into the parametrium with fixation can be relieved by alcohol injection but not by sympathectomy. Very late in the disease, pain is felt high up in the abdomen. This is due to extension of the disease above the sacrum into the aortic and iliac glands, the liver and elsewhere. This type of pain cannot be relieved by either sympathectomy or alcohol injections in the lumbar region. It is a good policy to inject alcohol intraspinally in all patients who have severe pain associated with carcinoma of the cervix, because even in women who have a hydronephrosis and other sources of pain some of the pain can be relieved.

**Carcinoma of Retained Cervix or Subtotal versus Total Hysterectomy**—Meigs relates the incidence and nature of cancer appearing in the retained cervix following supravaginal hysterectomy and adds facts to the arguments of the advocates of total or of subtotal hysterectomy. The study itself revealed a lack of understanding of the meaning of total or panhysterectomy and of subtotal or supravaginal hysterectomy. Total or panhysterectomy should mean removal of the entire uterus, fundus, body and cervix. These facts are not universally known or remembered and a questionnaire asking specifically whether the cervix was removed or not in a given hysterectomy was necessary before accurate figures could be obtained. When this fact was established there was a great reduction in the total number of cases discovered. The most important considerations are the large proportion of nulliparas developing cancer of the retained cervix, the large proportion of cases with fibroids in the series and the small occurrence of this cancer as compared to the general impression in the literature of today. Conservative surgery should be the rule, and the life of the patient the most important consideration. Careful examination of the cervix in the operating room before deciding the type of operation to be performed is essential. Total hysterectomy cannot be advocated in every case, but it should be if the reasoning of its proponents is correct. Supravaginal hysterectomy should not be advocated for every case, as a badly lacerated and infected cervix is a menace. The decision should be made by the individual operator in each individual case. Nulliparous cervixes are dangerous, and especially so are the cervixes left behind in nulliparas who have had fibroids.

**Early Symptomatology and Diagnosis of Gastric Cancer**—Harris points out that before the diagnosis of gastric cancer will be made early enough for much hope of cure from surgery most of the articles on ventricular carcinoma in the textbooks on medicine available to the general practitioner will have to be rewritten. The symptoms making up the generally accepted criteria for the diagnosis of cancer of the stomach, i. e., abdominal pain, nausea, vomiting, emaciation and anemia (cachexia), are late manifestations due to ulceration secondary infection and obstruction, and when they occur, in the majority of cases the patient has lost his chance for a cure by surgery or any other method of treatment. The earliest manifestation of gastric cancer in an individual more than 30 years of age, who is otherwise healthy, usually is what he calls "just a little indigestion." If such a person, as soon as he becomes stomach conscious, will consult the most capable gastro enterologist or internist available, who will take time for a thorough study of his case including roentgen examination by an expert roentgenologist, the diagnosis may be made early enough for the patient to be cured by an operation. In a small proportion of cases cancer of the stomach becomes engrafted on gastric ulcer, though it is extremely rare for a duodenal ulcer to become malignant. Therefore, if the individual who has an ulcer of the stomach is not speedily relieved of symptoms, or if there is a recurrence of symptoms after rest and dietary management for a few weeks in a hospital under a capable and experienced clinician, he should have an operation with the hope of removing the precancerous ulcer before it becomes malignant. The annual or semiannual physical examination may reveal symptoms that would cause the well informed physician to suspect cancer of the stomach earlier than now is being done. Therefore, if the public can be taught the need for the annual or semiannual physical examination by capable physicians, there is hope of decreasing the present high death rate from cancer of the stomach.

**Premedication and Inhalation Anesthesia for Tonsil and Adenoid Operations**—Gwathmey believes that the method described is safe because (1) premedication ensures a smooth induction of the anesthesia, (2) the anesthesia is at all times under perfect control, (3) the field of operation is dry and clear, and (4) postoperative contingencies and complications are eliminated. The basis for the technic presented rests on laboratory experimentation and clinical experience. It is desirable to give the child a sodium bicarbonate enema on admission. Thirty or forty minutes before operation, with the patient in bed, pentobarbital sodium dissolved in 1 ounce (30 cc) of water is given by mouth, or rectally in 4 cc of cold water.

if swallowing is difficult. The dose varies according to the age, size and condition of the patient. Generally, in children up to 7 years of age  $1\frac{1}{2}$  grains (0.1 Gm.) of the drug is given, from 7 to 10 years, 2 grains (0.13 Gm.), more than 10 years of age, 3 grains (0.2 Gm.). For adolescents the dose of the barbiturate is preferably increased, or a suitable amount of a morphine derivative may be added. More than 90 per cent of the author's patients are asleep within fifteen minutes. With care in lifting the patient from the bed (which should be accomplished by means of sheets or lifter in preference to hands) to the stretcher, he reaches the operating room asleep. When time is essential, the operation may be performed while the patient is on the stretcher. A small pillow is placed under the shoulders and neck.

**Use of Azochloramid in Infected Wounds**—Kennedy reports the results obtained in 108 cases of various infected wounds treated with azochloramid. Having tried various solutions and concentrations, he now uses only two preparations. Azochloramid solution 1:3,300 in physiologic solution of sodium chloride is used whenever irrigation or a wet dressing is desired. Azochloramid in triacetin 1:500 is used in all other circumstances, particularly for packing and dressing wounds with gauze which has been dipped in it. He suggests their use in the following general surgical conditions: 1 As a prophylactic in unclosed lacerated wounds, whether debrided or not. 2 As a prophylactic, in unclosed compound fractures after debridement. 3 As a prophylactic in abdominal operations, when owing to intraperitoneal infection it is believed advisable only to close the peritoneum and leave the remainder of the wound unsutured but packed with gauze. 4 In infected wounds and abscesses of all types except when gross slough or foreign bodies are present and have not been removed. This does not refer to an abscess wall, which the author has seen come out in its entirety after a few days. 5 In preparation of burned areas for skin grafting. 6 As a continuous wet dressing over fresh pinch grafts.

**Adrenal Insufficiency Resulting from Atrophy of Adrenals**—Weller believes that the cases presented not only stress the varied early manifestations of adrenal insufficiency but provide an adequate basis on which a description of its early symptomatology may be built. The clinical aspects including both

symptomatology and diagnosis of early adrenal insufficiency resulting from partial or total atrophy of the adrenals, are discussed. The features stressed are the existence of a definite but heretofore considered vague group of symptoms, from the time of onset to the termination of the destructive process in the adrenals, the manifestation of exacerbations in the adrenal insufficiency by nausea, vomiting, hypotension, hypoglycemia, drowsiness even to coma and atypical neurologic signs, the occurrence of exacerbations during periods of physical, emotional or endocrine stress, the frequent absence of pigmentation, and the relief of symptoms during the periods of exacerbation, in all but the terminal stages, by the administration of dextrose.

**Relation of Disease of Liver to Anemia**—The observations recorded by Wintrobe indicate that in cases of hepatic disease, except when loss of blood or a complicating infection is present, anemia, when it develops, is either of the normocytic or of the macrocytic type. The macrocytic anemia observed is in many respects like pernicious anemia, although it is rarely as marked as the latter, it is morphologically similar, if not identical. Spontaneous remissions in the anemia may occur. Intramuscular liver therapy was followed in several cases by definite reticulocytosis and a decrease of anemia such as occurs in cases of pernicious anemia. He assumes that the hepatic disease is the cause of the macrocytic anemia. In the cases of macrocytic anemia the hepatic disease was of such long duration and was so widespread through the organ that little functioning liver tissue remained. Macrocytic anemia appears to be especially common in cases of cirrhosis of the liver, and in this disease the illness is characteristically chronic and the lesions widespread. When damage to the liver is so extensive that storage is interfered with and when it has been of sufficient duration to permit exhaustion of the hematopoietic principle already present, macrocytic anemia develops. Experiments tend to support the belief that patients with disease of the liver and macrocytic anemia are able to utilize the extrinsic factor to form the hematopoietic principle. The ability to utilize the extrinsic factor may explain why in cases of hepatic disease with macrocytic anemia the anemia is rarely severe and the consumption of various amounts of active hematopoietic principle may explain the fluctuations in the degree of anemia that have been so frequently observed. The foci of blood formation observed in the spleens of the patients who had hepatic disease with macrocytic anemia are of considerable interest because such foci have rarely been observed in adults except in cases of pernicious anemia, osteosclerosis and carcinomatous replacement of the bone marrow and in rare cases of sepsis. Among the cases (132) of hepatic disease described there were only two in which any of the conditions known to be associated with the development of extramedullary hematopoietic foci were discovered. In each of these cases one small vertebral metastasis was noted. It is possible that other bone metastases were present which were not discovered. The presence of foci of extramedullary hematopoiesis in cases of chronic and widespread hepatic disease with macrocytic anemia is another point of similarity to pernicious anemia, in which, it has been already pointed out, blood formation in the spleen is common. The development of extramedullary blood formation may occur in the two instances as the result of the same fundamental abnormality, namely a deficiency in a necessary hematopoietic principle.

**Neuropathy in Diabetes**—Jordan and Randall made analyses of the various lipid constituents of fifty-two nerves from persons with diabetes and of twenty-three nerves from persons without diabetes. The average phospholipid, cholesterol and cerebroside content of the nerves from diabetic patients was considerably lower than that of the nerves used for controls. The nerves from the lower part of the legs of diabetic patients showed much greater damage than nerves from the pelvic level. This was not true in the one nerve from the lower part of the leg of a control subject as compared with the pelvic nerves from control subjects. The greater the vascular disease in a diabetic patient the greater the damage to the nerves. In two patients without diabetes who had arteriosclerosis this pathologic change was not found indicating that vascular disease is not the sole cause of neuropathy in diabetic patients. Previous inadequate control of the diabetes seems to affect the nerves

adversely to a slight extent. The severity and duration of the diabetes seemed not to affect the nerves, or else the effect was nullified by other factors. The chemical pathologic changes in the nerves of diabetic patients seemed to exceed or to precede the clinical manifestations of neuropathy. More complete studies of this chemical pathologic change to determine the effect of numerous factors are necessary before reliable statements can be made.

**Ergotamine Tartrate, Amniotin and Phenobarbital in Treatment of Migraine.**—Soltz and his associates give the results of the treatment of a group of migrainous patients with oral ergotamine tartrate, oral amniotin (Squibb) and phenobarbital. Certain types of patients respond to certain forms of therapy. On the other hand, it has not been shown that any of these types are resistant to other forms of treatment. Oral ergotamine tartrate is effective in male adults with either simple or ophthalmic migraine and in children of either sex, all but one of the children in the series presented the ophthalmic type of migraine. It is effective in women who suffer from the simple type of migraine, no definite statement can be made as to its value in ophthalmic migraine occurring in women. It is useful in women who are in the menopause. Negro women respond well to oral ergotamine tartrate therapy. Oral amniotin is frequently useful in women who suffer from either the simple or the ophthalmic type of migraine. The existence of the menopause, whether natural or artificial, appears to be immaterial in the response to treatment with oral amniotin. No men or children were treated with oral amniotin. With both forms of treatment women who have never been pregnant respond better than other women. Women whose migraine did not start until after the last pregnancy respond well to amniotin. Only two such patients were treated with ergotamine tartrate. Phenobarbital has been helpful in a small group of patients. Among these the ophthalmic type of attack predominates. No facts connected with abnormalities of menstruation or of the sella turcica appear to have any relation to success or failure with any of the modes of treatment. The age at the time of treatment or at the onset of the condition, and the duration of the migraine also appear to be without such relation.

**Physostigmine Derivative in Treatment of Myasthenia Gravis.**—Everts reports two cases of myasthenia gravis that were relieved of symptoms and restored to health by the oral administration of a physostigmine derivative (prostigmine) continued for a period of months. The oral administration is effective and has distinct advantages over the hypodermic use of the drug. The best results were obtained by doses of 30 mg given three times a day. The oral administration of the drug is safe, does not produce gastric or intestinal disturbances, can be continued for indefinite periods and is a satisfactory method of therapy in myasthenia gravis.

\*Diarrhea and Typhoid Infections Elizabeth Chant Robertson Toronto —p 37

**Diarrhea and Typhoid Infections.**—Robertson cites the following: 1 Of a group of nine boys who drank unboiled river water, eight developed gastro-intestinal disturbances within forty-eight hours, the ninth did not show any early reaction but developed paratyphoid seven days later. 2 Of a family of seven who were exposed to a case of typhoid, four showed early gastro-intestinal disturbances, one showed no ill effects but had had typhoid previously, and one had no early upset but developed typhoid ten days later. The seventh member of the family, an infant, showed no symptoms. 3 Of a large group of children, an unknown number of whom were exposed to infection with *Bacillus typhosus*, about 30 per cent developed gastro-intestinal disturbances within forty-eight hours after exposure. Eleven of the children developed typhoid and only one or possibly two of these showed any early reaction after exposure. It is possible that the immediate gastro-intestinal reaction prevents the typhoid bacilli from invading and setting up a severe infection.

**Diagnosis of Carcinoma of Pancreas.**—Sones points out that there is no clinical syndrome singularly characteristic of carcinoma of the pancreas. There are no physical, laboratory or roentgen signs which in themselves are final in the diagnosis. In a case of cachexia with loss of weight and strength, deep progressive jaundice, hard boring epigastric pain radiating to the back and affected by posture, palpable epigastric tumor which is fairly well fixed and tender, palpable gallbladder, abnormal blood sugar level and positive roentgen observations, one has all the cardinal symptoms and signs present for a reasonably accurate clinical diagnosis of carcinoma of the pancreas but the actual computation by percentages would

reveal the fact that all these features are present in the same case in only one out of at least 200 cases. In the great majority of cases many of these are lacking or indefinite, so that a satisfactory diagnosis is difficult or impossible, but it seems fair to say that with cachexia, weight and strength loss as one, in addition to any two of the remaining features, one has sufficient evidence for a presumptive diagnosis.

### Protein Studies in Atrophic and Hypertrophic Arthritis

—Davis determined the total plasma protein albumin, globulin, fibrinogen, globulin fractions pseudo I and II and euglobulin and sedimentation rate on ninety subjects. His paper deals only with changes occurring at various stages of arthritis. The globulin fraction tends to rise in atrophic (rheumatoid) arthritis. The greatest change takes place in the euglobulin fraction. Albumin tends to fall in atrophic arthritis. There is little if any change in the protein fraction of those ill with hypertrophic arthritis. Evidence is presented to show that atrophic arthritis is an infectious disease while hypertrophic arthritis is not. Theoretically a diminished sedimentation rate is not always an accurate index of improvement as accomplished by vaccine, for a rise in globulin has been produced by certain vaccines and this alone might increase the sedimentation rate. This has not been the author's experience in using hemolytic streptococcus vaccine. The fibrinogen content usually rises in atrophic arthritis but not in proportion to the globulin rise. Restriction of protein in the diet of the atrophic arthritic patient might at times be dangerous. Vitamin deficiency and malnutrition may play a part in the protein changes in atrophic arthritis.

**Chronic Atrophic Arthritis and Effect of Diet and Insulin on Symptoms and Respiratory Metabolism** —Bowen and Lockie observed eight women, from 18 to 65 years of age, with advanced atrophic arthritis for a period of from fifteen to sixty five weeks during which time they were fed a high carbohydrate diet. The patients had lost from 25 to 50 pounds (11.4 to 22.7 Kg). Seven of the patients received insulin for the purpose of observing its action on increasing appetite and the influence of the reduction of blood sugar on the arthritis. All patients were observed for varying periods on the diet alone before insulin was administered. Carbohydrate was given to them in many forms. After this preliminary study further nutrition was attempted by the use of insulin up to the point of the patient's tolerance. The weight curve was not conspicuously higher during the period of insulin administration, nor was the amount of food ingested greatly increased. Following the sudden withdrawal of insulin saline solution subcutaneously was substituted. The first three patients who had been under observation for the longest periods, made the greatest weight gains 42.50 and 24 pounds (19, 22.7 and 11 Kg). They also made the greatest clinical improvement. Two patients even though they did ingest adequate calories, failed to gain both had the maximal devastation of the disease. One patient, who had gained a lesser amount also improved remarkably. Clinical improvement that was

observed in these patients cannot be ascribed to a single measure, because several factors were obviously operating—rest, freedom from worry and exposure, and a large amount of vitamin C. As far as possible, other adjuncts were employed in a minimal degree. The high carbohydrate diet did not produce any exacerbation of the arthritic process. The respiratory metabolism was studied in seven of the cases. Only one patient had a temporary slight lowering of the rate, which was possibly due to an antecedent respiratory infection. The rates were found to be steady throughout the period of observation and were uninfluenced by increasing body weight. The trend of the postabsorptive respiratory quotients, even though they showed in some cases rather wide variations, was approximately level throughout. The quotients during the periods of insulin administration were not altered. The average quotient was found to be slightly higher than that of persons who eat the ordinary mixed American diet. It then seems that the seven patients were able to use carbohydrate normally. The authors do not believe that a high carbohydrate diet has any special efficacy in the treatment of chronic atrophic arthritis, but they do stress the importance of overnutrition in the management of such patients when they are undernourished.

**Treatment of Atrophic Arthritis with Leukocyte Concentrate** —Hartung used leukocyte concentrate in atrophic (rheumatoid) arthritis because of the nucleic acid content of these cells and because he thought that normal leukocytes might contain a hormone lacking in patients with atrophic arthritis. Ten patients with atrophic arthritis were selected by the usual criteria. Their condition ranged in severity from markedly generalized, crippling deformity in a child 10 years of age to mild but definite arthritis in elderly subjects. No case can be considered cured. Six patients show decided symptomatic and general constitutional improvement. In the remaining four patients, improvement was only slight or questionable. Improvement consisted of a decrease in pain, an increase in joint motion and a feeling of increased strength and well being. These changes were not, however, accompanied by improvement in the blood picture or in the sedimentation rate. It is clear to the author that intraglutal injections of leukocyte concentrate have a definite beneficial effect in some cases of atrophic arthritis. The effect is apparently in no way specific. In view of the lack of change in the sedimentation rate it appears that its effect is constitutional and only indirectly affects the arthritis. Its mode of action is obscure. The amount of nucleic acid present in the injected leukocytes is not sufficient to affect the blood picture. The beneficial effect may be purely a nonspecific protein reaction, but the effect was obtained more quickly, was more lasting and in every way far superior to that obtained by any foreign protein used previously by him.

- \*Defenses of the Air Passages (Semon Lecture 1935) S. C. Thomson —p. 1  
Laryngeal Disease of the Emperor Frederick J. Colledge —p. 31

**Defenses of Air Passages**—Thomson limits his review of the defenses of the airways to the local means of protection in normal conditions of health. These are reinforced by such prophylactic weapons—particularly in disease—as antitoxins and other antibodies, opsonins and phagocytosis, bacteriolysis, leukins and other germicidal substances, and the army of reserve defenses that maintain the normal state of immunity. These local defenses are so effective in health that it is difficult to produce pulmonary infections by inhalation or insufflation of organisms under normal conditions. He discusses the complexity and perfection of these defenses and hopes to encourage interest in normal processes as a necessary first step to the study of disease. Biology is opening up possibilities of discoveries that will enlarge the conquests of Pasteur, Koch and Lister. This may lead to knowledge that will avert or cure many of the common human ailments. These studies should help to explain why the removal of a focus of infection or why operations, however radical and brilliant, sometimes fail to cure.

**Therapeutic Action of Iron**—According to Wills, iron is absorbed chiefly in the duodenum, but the stomach and the whole of the small intestine may take part. The upper part of the alimentary tract is an all-important area in hemato-poiesis, the surgeon should avoid too ruthless an exploitation of this territory. In health the absorption of iron by the stomach and small intestine may be expected to be equalized by the loss through the colon. The administration of iron to normal men does not affect the blood count, but much of the iron may be retained in the body. There is a minimal effective dose of iron. In addition to the physiologic states that increase the requirement of iron, there are pathologic conditions that impair its absorption and give rise to a conditioned deficiency. "The most important is achlorhydria. The therapeutic action of iron can be enhanced by certain procedures that facilitate the absorption of iron. Bethell and his co-workers showed that a dosage of 300 mg. a day of reduced iron was ineffective when given in three divided doses of 100 mg. but

was effective when given in ten divided doses of 30 mg., this seems to be a pure absorption phenomenon. In experimental animals iron can be absorbed and stored in the liver but cannot be converted into hemoglobin unless copper also is present, this is apparently a pure utilization phenomenon. It is difficult to demonstrate the action of copper in man, in whom deficiency of copper is excessively rare. The "average effective dose" of a preparation of iron may be defined as the dose that produces an average increase of more than 1 per cent of hemoglobin a day in a sufficiently large sample of patients with achlorhydria and anemia, when the initial hemoglobin level does not exceed 50 per cent and when the period of observation is not less than twenty-five and not more than forty days. Iron is most active when given by injection, but in practice parenteral administration is contraindicated by its dangers. The therapeutic dose of iron by injection (iron and ammonium citrate equivalent to 32 mg.) is so close to the toxic dose (from 48 to 80 mg.) that effective treatment can hardly be given by this route. The therapeutic activity of preparations of iron by mouth is proportional to their solubility and to the ease with which they yield free ions of ferrous iron. The soluble ferrous salts are the most active. The utilization of an average effective dose of ferrous iron is approximately 20 per cent, and, if minimal effective doses of ferrous iron are prescribed, between 50 and 100 per cent of the dose ingested may be utilized for hemoglobin formation. Reticulocyte crises and repair of anemia may be observed with a daily dosage as low as 22 mg. of ferrous iron by mouth. To a large extent, iron is used to repair deficiencies that would not have occurred had the diet been satisfactory.

**Gastric Acidity and Its Significance**—Apperly suggests that hyperchlorhydria and the symptoms associated with it might be diminished by removal to a warm climate, artificial fever, heat treatment, bleeding and the substitution of oxides and nonabsorbable bicarbonates for the usual sodium bicarbonate treatment, since the latter salt in large amount, by increasing plasma carbon dioxide, may actually raise gastric acidity. Certain of the hypo acid dyspepsias are more likely to be influenced by attention to the underlying anoxemia or acidosis than by direct local treatment. A search for the causes of a low plasma carbon dioxide may be fruitful, since it may give a clue to the underlying pathologic conditions. In dealing with cases in which achlorhydria or hypochlorhydria is associated with anemia, it might be well to investigate which of these conditions is primary—i. e., whether one is dealing with an anemic achlorhydria or an achlorhydric anemia (Witts). Gastric acidity after a meal is chiefly a function of the blood carbon dioxide. In normal persons this is regulated by the hemoglobin content of the blood, by the ratio of the pulmonary vital capacity to body weight (or surface) and by temperature. Under abnormal conditions anoxemia, anemia, altitudes, pregnancy, nephritis, fevers, diabetes, severe exercise and lowered physical fitness may diminish plasma carbon dioxide and therefore gastric acidity. Asthma and emphysema, which raise plasma carbon dioxide, would be expected to raise gastric acidity, while encephalitis, irradiation and certain cardiac conditions, which lower plasma carbon dioxide, would be expected to lower gastric acidity, but these effects have not been investigated. The acidity of the gastric juice is a rough measure of the alkali reserve of the blood (except in marked anemia), while the rate of gastric evacuation would seem to be influenced partly, at least, by blood  $pH$ . A consideration of the possible causes of such variations of plasma carbon dioxide and  $pH$  may give valuable hints as to the pathologic conditions underlying certain dyspepsias. There is a direct relationship between the red cell content of the blood and gastric acidity. When the former falls to about half or two thirds normal (on the average), free acid disappears from the stomach. A distinction is therefore made between the achlorhydric anemia of Witts and anemic achlorhydria.

- Variability of Erythrocyte Sedimentation A Kaminli—p 8

**Epituberculosis in Adults**—Benda and Mollard define peritocal infiltration as an inflammatory reaction around a focus and epituberculosis as an inflammation so large around a focus so tiny that the relations between cause and effect are apparently reversed Stated in another way the latter reaction has an importance apart from the focus around which it developed There is thus no essential reason why epituberculosis should not develop in adults as well as in young people In corroboration of this view they recently observed two adult patients in whom the roentgen and physical examination demonstrated this type of reaction These patients did not show any other tuberculous focus Furthermore they state that in tuberculous patients who are regularly followed it is not unusual to see sudden pulmonary condensations, which quickly disappear and involve another region of the lung Finally, epituberculosis in adults is sometimes seen following therapeutic procedures The authors conclude that their conception of epituberculosis is more general and more elastic than that of most and comprises all the perifocal reactions which reveal a focus while temporarily concealing it It appears incorrect to them to limit epituberculosis to a certain age a slow evolution or a silent roentgenologic period

- Diagnosis of Crural Hernia P Livraga—p 869

**Glycogenic Functions of Liver**—Lauro gives the name of associated syndrome of the right side of the abdomen to a complicated pathologic process of diffuse alterations of several abdominal organs of the right half of the abdomen He made determinations of the glycolytic functions of the liver by means of the test of provoked hyperglycemia after the administration of levulose or dextrose in three groups of patients suffering from different types of syndrome of the right side of the abdomen (simple or in association with duodenal ulcers or cholecystitis) The author reaches the following conclusions: There is a disturbance of the metabolism of the carbohydrates

in all patients with a syndrome of the right side of the abdomen. The metabolic disturbance is more intense in the complicated type (duodenal ulcer or cholecystitis) than in the noncomplicated type of the syndrome. Levulose used in producing hyperglycemia gives more precise results on the glycolytic functions of the liver than dextrose given for the same purpose (83 and 38 per cent, respectively). The insufficiency of the glycolytic functions of the liver does not indicate by itself complete liver insufficiency, but added to the insufficiency of other liver functions under the same condition reported in the literature and to the anatomic alterations seen in the liver of those patients by Leotta and Rindone, it shows that the liver is more or less involved in the pathologic process. The author points out the advisability of performing determinations of the liver functions in all patients with a syndrome of the right side of the abdomen previous to the performance of any abdominal operation, with the aim of preventing a postoperative complication from liver insufficiency that existed before the operation but was not diagnosed.

Suction Treatment of Acne Vulgaris A. Skutta—p. 137

**Suction Treatment of Acne Vulgaris**—Skutta thinks that although general factors play a part in the development of acne vulgaris the cutaneous manifestations are nevertheless greatly influenced by local conditions. He shows that the obstruction of the sebaceous glands (comedo) that is the retention of the cutaneous sebum is the cause of the local symptoms. In view of the mechanical nature of this process, a mechanical therapy seems indicated which formerly was effected chiefly by means of expression. However, since expression was not quite satisfactory, the author devised a suction method. He shows that since the vacuum in addition to its mechanical also exerts a biologic action on the tissues the treatment by means of a vacuum is really more than just a mechanical treatment. Besides counteracting the retention of sebum it also has a favorable effect on inflammatory manifestations. After showing how the retention of sebum causes the cutaneous symptoms of acne the author describes the various forms of suction cups that he attaches to the apparatus. He uses different types of cups for the cystic retention of sebum for the removal of comedones and for the treatment of the inflammatory manifestations. The suction apparatus can be operated with the water vacuum pump or with an electric pump. In addition to the local suction treatment the author also employs general causal measures (dietetic, endocrine and so on). Three years of experience with the combined suction and general treatment convinced him that it produces good results and especially reduces the cosmetic defects that are connected with acne.

Present Status of Experiences with Meinicke Clarification Reaction II in Cerebrospinal Fluid K. H. Dombrowsky—p. 219

**Roentgen Reaction Elicited by Medicament**—Uhlmann describes the history of a woman aged 45 who received roentgen irradiations on account of uterine carcinoma. The roentgen rays were applied to one abdominal field and two dorsal fields. No cutaneous disturbances developed in the course of the irradiations but ten days after the last ray treatment the irradiated regions showed an intense erythema and the entire body became covered with a scarlatiniform exanthem which was especially severe on the sides of the trunk and on the thighs. The eyelids were swollen and the lower parts of the legs were edematous. At times the skin was extremely itchy. The patient felt poorly. On the basis of the clinical manifestations a medicinal toxicoderma was thought of. At first the patient stated that she had not taken anything but finally

admitted that she had taken sleeping powders (barbituric acid derivatives). It could not be definitely determined how large the doses had been, but there were indications that she had taken more than eight tablets daily. The further course of the disorder definitely confirmed the diagnosis of medicinal toxicoderma, for after the patient discontinued taking the tablets the cutaneous manifestations disappeared. The author points out that not only the patient and her relatives but also a physician had considered the disorder a generalized roentgen exanthem. To be sure, the author concedes the possibility of the development of a generalized exanthem following irradiation with roentgen rays, but he doubts that the roentgen rays are the only cause of such exanthems, pointing out that in all the cases which came under his observation either an accidental concurrence of septic exanthems with the irradiation or a suddenly developing erythroderma in psoriasis could be demonstrated, so that the roentgen irradiations at most could be suspected of being an eliciting factor. In thousands of cases the author never found a true generalized roentgen exanthem and he says that other authors and large institutes report the same.

### Klinische Wochenschrift, Berlin

15 145 184 (Feb. 1) 1936 Partial Index

Abnormal Diastase Values and Blood Sugar Content G. Jorns—p. 167

**Influence of Vitamin C on Blood Picture**—Lufinger and Gaetgens after pointing out that vitamin C has been found helpful in various forms of capillary hemorrhages and in gynecologic bleedings, call attention to an observation indicating that vitamin C also exerts a favorable influence on the white blood picture. They describe the clinical history of a woman, aged 35 who had a myeloid leukemia. By means of the intra-venous injection of large doses of ascorbic acid (100 mg twice daily for ten days) it proved possible nearly to normalize the white blood picture in a comparatively short time and also to exert a favorable influence on the red blood picture. The woman recovered and was able to work again. Various factors seem to indicate that an action on the bone marrow is chiefly responsible for the efficacy of this treatment.

**Basophil Stippling of Erythrocytes**—Rosegger points out that basophil stippling of the erythrocytes was first observed by Askanazy in the blood of anemic patients but that after Sabrazes called attention to its significance in the diagnosis of lead poisoning it was regarded by many as proof of an existing lead poisoning. The author considers this opinion erroneous and points out that a small number of erythrocytes with basophil stippling appear even in the blood of healthy persons. Discussing the origin of basophil stippling, he shows that the staining of every cellular element is dependent on its electrical charge, which is different in the nucleus, the nucleoli, the protoplasm and so on. If the hydrogen ion concentration of the cell surroundings is altered the electrical charges are likewise changed. A portion of the cell that formerly had an acid reaction may now become basic and vice versa. The author found that the point at which acidity changes into alkalinity, that is the iso-electric point, is in the majority of cases the same for the basophil stippling, for polychromasia and for the reticulofilamentous formation. He concludes that this favors the common origin of these phenomena. He says that the diagnostic value of the basophil stippling is slight, because it is detected in a large number of pathologic conditions. It is comparatively frequent in the diseases of the blood, particularly pernicious anemia in which it is found at the beginning of the stage of remission. It occurs also in certain occupational diseases and in renal disorders. The presence of basophil stippling indicates increased irritability of the bone marrow.

**Abnormal Diastase Values and Blood Sugar Content**—Jorns points out that surgical treatment of diabetes mellitus by means of ligation of the pancreatic duct has proved unsuccessful. Ligation of the excretory duct of the parotid gland, which had been suggested by other investigators produced only a temporary effect. The latter intervention had been suggested because it was assumed that the parotid produced an insulin-like substance which following ligation of the duct and stasis of the secretion, would become absorbed in larger quantities. However, this explanation was refuted. Later it was assumed that the reduction in the blood sugar values which became manifest after the ligation of the duct of Steno was a result of an increased resorption of the salivary diastase. Some investigators corroborated this assumption by experiments but more critical studies disclosed that the behavior of the blood sugar is entirely independent of the concentration of diastase in the blood. The author studied the diastase and blood sugar values in cases of parotitis and found them normal in the majority of cases. He ligated the excretory duct of the parotid gland in rabbits and during the first six or eight days after this intervention he studied the blood sugar and the diastase values. He found that the diastase values increased shortly after ligation, but that this soon subsided and the blood sugar values showed no changes. He reaches the conclusion that as yet there is no proof for an interdependence of the blood sugar and the diastase contents.

Significance of Serologic Examination of Tuberculosis F E Haag and E L Schiedges—p 195

Influence of Insulin on Motor Chronaxia of Rabbits H Reimers—p 199

**Influence of Nicotine on Iodine and Cholesterol Content of Blood**—Strauss and Scheer direct attention to the fact that not only smokers are exposed to the injurious effects of nicotine but also workers in tobacco factories and persons who work with parasitocides that contain nicotine solutions. In animal experiments and in clinical observations it was determined that nicotine may cause degenerative changes in the myocardium and sclerotic processes in the central and peripheral vessels. The question arises whether and to what extent the thyroid (in connection with other secretory glands) and the cholesterol metabolism are involved in changes that develop as the result of nicotine intoxication. In order to determine the thyroid involvement, the iodine content of the blood was watched and the control of the cholesterol content of the blood appeared desirable in view of its correlation with the epinephrine metabolism and in view of the vascular disturbances that develop after nicotine intoxication. In observations on human subjects (smoking with inhalation) and on animals (injection of nicotine), two types of iodine curves could be differentiated. The first indicated an increase in the iodine content in acute nicotine intoxication, the second indicated a reduction of the iodine content in acute intoxication. The first was found chiefly in persons who smoke only occasionally, are hypersensitive to nicotine or have hyperthyroidism. The second was found in habitual smokers and in persons with hypothyroidism. In animals the curve showed an analogous behavior in acute and chronic nicotine intoxication. The curve indicating the cholesterol content of the blood was less characteristic. The thyroids of the animals with chronic nicotine intoxication showed histologic changes in the form of thyroiditis or atrophy.

**Bactericidal Power and Antitoxic Action of Vitamin C**—After pointing out that in previous studies he was able to show that, in addition to an alimentary C-avitaminosis (scurvy), there is also a toxic form that develops in infectious diseases such as diphtheria, von Gagy reports his studies on the bactericidal and antitoxic action of vitamin C. He found that virulent pathogenic bacteria have a high degree of sensitivity to vitamin C. If diphtheria bacilli are put in a solution of vitamin C

they retain their capacity for growth up to an exposure of two hours, but if the exposure to vitamin C has lasted four hours the capacity for growth disappears. Even bacilli that have been under the influence of vitamin C for two hours have lost their virulence to a considerable extent. Whether the bacteria that have been killed by vitamin C action stimulate antibody formation has not been determined as yet. Not only are the bacteria impaired by vitamin C but the vitamin C is also impaired by the bacteria. There is a parallelism between the sensitivity to vitamin C and the impairing action on it. Diphtheria bacilli lose these two characteristics in the course of recovery. Vitamin C has a prophylactic value in that it exerts an inhibiting effect on the bacterial flora of the organism. It has a therapeutic effect, because it detoxicates and reduces the virulence. The development of a toxic C-avitaminosis in infectious diseases is due to the fact that the C factor is destroyed in the act of detoxicating and binding. The author concludes that there is theoretical justification for the administration of vitamin C in certain infections and communicable diseases, but he admits that the time and manner of the practical application have not been determined as yet.

What Practitioner Should Know About Lymphogranuloma Inguinale H Lohé—p 141

\*Diagnostic Significance of Distant Symptoms in Ulcers of Stomach

and Duodenum H Diefenthaler—p 149

Diagnosis of Open Foramen Ovale H Bix—p 150

Treatment of Pneumonia K Nissen—p 151

**Distant Symptoms in Ulcers of Stomach and Duodenum**—Diefenthaler calls attention to the fact that Oefelein observed in patients with gastric and duodenal ulcers the presence of a unilateral dorsal reflex in response to stroking the skin in the region of from the seventh to the twelfth dermatomes. Oefelein found also that this reflex was generally missing in healthy persons and that it disappeared after the gastric or duodenal ulcer had healed. The author in studying this reflex, made the same observations on healthy persons as did Oefelein, that is, he found the reflex missing. However when he studied the reflex on patients with internal disorders he discovered it in approximately half of the patients. To be sure it was rarely unilateral but was usually elicitable by stroking both sides of the back although it was not always equally intense on the two sides. Among the patients in whom the reflex was elicitable there were a number who had a gastro-intestinal ulcer. However, the reflex was absent in approximately one third of the patients with gastro-intestinal ulcers and it was only slight in others, it was clearly elicitable in about half of the patients with ulcer. A review of the cases without gastro-intestinal ulcers, in which the reflex was positive and their comparison with the ulcer cases in which the reflex existed disclosed that the dorsal reflex is elicitable especially in patients in whom a hyperesthetic zone exists in the back. He thinks that the dorsal reflex has some connection with this hyperesthetic zone and points out that for this reason it has only slight value in the diagnosis of gastric and duodenal ulcers. Onodera has stated that in patients with ulcers of the stomach or the duodenum there is a point that is painful to pressure at the site of insertion of the median gluteal muscle between the anterior superior iliac spine and the sacrum. The author found this painful point only in rare cases and concludes that its diagnostic significance is slight.

Dermatoses in Anemic Patients P Chevalier—p 120

Diseases of Testes W Richter—p 122

Pulmonary Changes in Boeck's Sarcoid Margarete Saacke—p 124

**Significance of Porphyrins in Lead Poisoning**—Carric shows that lead poisoning is the most frequent form of the toxic porphyrias, other forms of which may be caused by the barbituric acid derivatives by sulfur preparations and by other toxic substances. He points out that, in view of the fact that porphyria of unknown origin has the same clinical aspect as

toxic porphyria it is necessary to search for a toxic cause, particularly lead in all cases of porphyria. After discussing the structure of the porphyrins and their chemical relation to the blood and bile pigments, he states that Schreus classifies the porphyrias under primary forms (elimination of porphyrin I) and secondary forms (elimination of porphyrin III). The classification shows that toxic porphyria (lead poisoning) belongs to the secondary forms. Then the author discusses the demonstration of the porphyrias by means of various methods and he evaluates the diagnostic significance of the porphyrins. In this connection he points out that, although a single test may give information about the porphyrin values, repeated tests are more reliable. It has been determined also that there is a relationship between the quantitative elimination of porphyrin and the severity of the symptoms of lead intoxication. In discussing the effects of the porphyrins the author stresses their action on the blood vessels and says that the frequently observed increase in the blood pressure as well as the oliguria can be ascribed to such vascular effects. Further attention is called to the relations between the porphyrins and the calcium metabolism and to the affinity of the excessive porphyrins for the bones. In the treatment of lead poisoning an alkaline diet is advisable and eventually alkaline substances may be administered. Calcium therapy has likewise been recommended as helpful and liver therapy in the form of the injectable extracts has proved effective.

**Striae Distensae as Hypophyseal Symptom**—Schilling reports the clinical histories of two young men who had apparently opposite disturbances (obesity and emaciation) but both of whom had the bluish red striae distensae occasionally seen during pregnancy. The first patient who at the age of 11 years had sustained a peculiar accident with probable fracture of the base of the skull, had the symptoms of Cushing's pituitary basophilism. The second patient presented the aspects of Marfan's symptom complex with hypophyseal tumor, designated by him as dolichostenomelia and later called arachnodactylia. The author shows that the striae distensae are a clinically important general symptom indicating the various forms of hyperfunction of the anterior lobe of the hypophysis. In Cushing's syndrome this hyperfunction concerns chiefly the basophil cells, whereas in the almost diametrically opposed Marfan type (arachnodactylia) the hyperfunction probably involves chiefly the eosinophil cells. It is possible that a slight increase in the growth hormone of the eosinophil cells, if it begins with the fetal period results in the Marfan type if there is a considerable increase in the growth hormone of the eosinophils during the period of growth, giant growth may be the result, and in older persons it may cause acromegaly. The Marfan type is not necessarily hereditary, but apparently it may be caused by a conditional disturbance in the formation of the hypophysis. This disturbance may later cause the development of hypophyseal tumors that act in the same manner. The excessive elimination of the luteinizing hormone in the urine of a precocious boy with the Marfan type and hypophyseal tumor indicates that this

hormone is produced in other than the basophil cells of the hypophysis, but the excessive quantity of this hormone indicates also that it is of hypophyseal origin, since production in the placenta would be impossible in this case. Moreover it corroborates the clinical supposition of a tumorous degeneration of the anterior lobe of the hypophysis, the structure of which does not seem to correspond to the basophil or eosinophil adenomas.

Significance of Sensory Nerve Pressure Reflexes (According to Kehrner Münster) in Eclampsia and Preeclampsia H Hoffmann—p. 163

**Use of Blood Transfusion in Puerperal Fever**—Erbslohn reports the results obtained with blood transfusions in the treatment of seventy-five cases. Blood transfusion was resorted to in nearly all cases of puerperal sepsis except those in which the septic process had already become localized. In the latter cases the author regards blood transfusions as useless, except when a simultaneously existing secondary anemia has to be treated. Blood transfusions were dispensed with also in cases of cardiac and circulatory weakness in which there existed signs of insufficiency or in cases with stasis in the lesser circulation particularly with extensive septic pneumonias. Other contraindications were endocarditis, extensive thrombophlebitis, severe renal disorders and hepatic metastases. In the cases in which blood transfusion was employed it was combined with all other methods that are customarily employed in the treatment of puerperal fever. There were twenty-seven fatalities among the seventy-five cases in which blood transfusion was employed; that is the mortality rate was 36 per cent. The author points out that this figure corresponds approximately to the results that have been obtained with the expectant conservative treatment. A number of the cases that had a fatal outcome in spite of the blood transfusion were of foudroyant sepsis, in which the defense powers of the organism were completely inadequate to check the infection. In other cases the condition was already rather desperate (beginning circulatory weakness and multiple septic metastases) and blood transfusion was a last resort. On the other hand, there were nineteen extremely grave cases among the forty-eight in which recovery occurred after blood transfusion. In the severe cases of sepsis the author gained the impression that the transfusion is of little avail in those instances in which the hemoglobin content and the number of erythrocytes are almost normal, however, it produces favorable results in the cases in which great loss of blood has produced a secondary anemia or in which the septic process has reduced the hemoglobin and erythrocyte values. In the latter cases a single transfusion is as a rule inadequate and it is advisable to control the blood picture from time to time and repeat the transfusions as often as the blood status indicates. After admitting that in spite of blood transfusion the mortality of puerperal fever or sepsis is still rather high, the author calls attention to the so called immunotransfusion and to the transfusion of convalescent blood. The first of these two procedures involves loss of time as well as considerable inconvenience to the donor (vaccination, chills). The second method is less complicated but it presents the problem of securing a suitable donor.

**Treatment of Empyema and Blood Transfusion**—Schlegel stresses that experience has shown that the more conservative methods produce better results in empyema of nurslings and small children. He says that at his clinic pure-

tures are being postponed as long as possible, generally as long as there are still inflammatory processes in the lungs. The first aim of the treatment should be to strengthen the child's organism in its defense against the micro-organisms. In fourteen of thirty cases it proved possible to obtain retrogression of the empyema by rest, application of heat, proper feeding and blood transfusions. In ten children one or several punctures were made, either because the general condition indicated it or because symptoms of displacement appeared. A drain was introduced in six cases in which the empyema rapidly filled again. The author stresses the great value of blood transfusions in children with empyema. He says that this measure not only has a favorable effect on the local symptoms but also improves the general condition to such an extent that conservative measures are often adequate in counteracting the empyema. He deplors that the method was not satisfactory in nurslings, as four of the six fatalities from empyema concerned nurslings weighing less than 4,600 Gm. In describing the method of blood transfusion he says that he employs donors of the same blood group. For technical reasons he uses citrated blood. He gives a preliminary injection of 5 or 10 cc and five or six hours later performs the main transfusion in the course of which he transfuses from 15 to 20 cc for each kilogram of body weight.

**Homologous Arteries and Localization of Disease—** Wiesner selected the brachial artery for his comparative studies on homologous arteries. A factor that induced him to select this region was the statement of a dermatologist that freezing of the left hand is observed more often than of the right hand. Since there is a connection between the effect of cold and the blood supply, the author decided to investigate whether anything could be found in the vascular apparatus that would explain this. He states that homologous vascular regions of the brachial arteries in the same person show in the majority of cases different widths of the lumens and different wall thicknesses. This asymmetry of the vessels is usually the result of an increase in the size of the right brachial artery. There are histologic changes that correspond to the differences in size in the arteries of the two sides. During the first months of life the difference in the right and left brachial arteries is not yet apparent; however, it begins to appear during early childhood. The fact that the right brachial artery is wider and thicker makes it appear likely that the change has some connection with right handedness. It might be a process of adaptation, for the greater activity of the right hand and arm requires a greater blood perfusion of the tissues. From this point of view it appears that the morphologic changes are the manifestation or result of the changed functional activity. The author stresses that the brachial artery is only one example and that similar conditions may be found in other regions. He was induced to study the brachial artery because freezing of the left hand is more frequent than freezing of the right. He suggests that this might be due to the fact that in the narrower vessel the vascular tonus is greater than in the wider vessel and that, if as the result of the cold the tonus is further increased, the blood stream encounters greater resistance in the left brachial artery. However it is also possible that the wider vessel has a neuromuscular apparatus that functions better in response to the stimulus of cold and thus effects a better blood perfusion under the changed conditions.

**Oliguria Resulting from Sodium Chloride Retention**—Lauda and Wichtl describe two cases of oliguria caused by the retention of sodium chloride. In one case the condition

was rather mild in that, after a certain degree of retention had been reached, the sodium chloride was eliminated and the formation of edema was thus prevented. In the other patient however, the condition was grave in that the retention of sodium chloride resulted in anasarca. In the second case the true nature of the disorder had not been recognized. The severe pains in the renal region, of which the rather neuropathic patient complained, had led to two decapsulations and finally to the extirpation of a normal kidney. In view of the latter case the authors discuss the classification of oligurias. They stress that thus far there is proof only for a primary oliguria caused by primary oligodipsia and for oliguria resulting from the retention of sodium chloride whereas there are no proofs for the existence of a constitutional renal oliguria or for an oliguria caused by primary retention of water in the tissues.

- \*Cobra Toxin as Analgesic in Gynecologic Carcinomas J Nekula—p 328

**Radium Treatment with Exteriorization in Cervical Carcinoma—**The difficulties that are encountered in the course of radium treatment of tumors in the small pelvis induced Daels to resort to the exteriorization of the small pelvis. To do this, he makes a transverse incision into the abdominal wall 1 cm above the pubic symphysis and above Poupart's ligament, then ligates the epigastric vessels, sutures the lower edge of the peritoneum to the skin above the symphysis and the inguinal canal, severs the peritoneum of the posterior half of the pelvic inlet up to the pelvic mesocolon, sutures the upper edge of this line of incision to the parietal peritoneum of the anterior abdominal wall, sutures the lower edge to the skin and thus forms a new diaphragm at the level of the promontory. He found it advisable to wait from three to five days after the exteriorization before beginning the radium treatment. Then the radium tubes can be introduced without difficulty to the right and left of Douglas' pouch and to the right and left of the vesico uterine fold. In the beginning the author alternated between periods of treatment and periods without treatment (four or five days in length) but later he found that the treatment could be continued uninterruptedly for from ten to eighteen days. He stresses as the advantages of the method the possibility of uniform irradiation of the small pelvis, the prevention of injuries to the connective tissue, the possibility of prolonged weak irradiations, the absence of retention of infected secretions from the cancerous focus, which frequently occurs in the case of intra-uterine or intravaginal irradiation and, finally, the possibility of careful control.

**Cobra Toxin as Analgesic in Gynecologic Carcinomas**—Nekula tested the analgesic action of cobra toxin in ten patients with genital carcinoma. He says that the cause of the analgesic action of cobra toxin is not definitely known as yet but that it is probably the result of a paralytic effect on the sensory nerves. The toxin of the Indian cobra (*cobra de capello*) is used for analgesic purposes because it contains the most neurotoxins and the least hemolysins of any snake venom. The author obtained a reduction of pain in all ten cases in which he employed the cobra toxin, and in two cases he was able to suppress the pains completely. He injected the toxin subcutaneously in the region of the deltoid muscle. For the cutaneous disinfection alcohol was used (never tincture of iodine), and it is stressed that the simultaneous internal medication with iodine is likewise inadvisable. With regard to the dosage he says that the best results were obtained when small doses (about 10 mouse units) were administered every second day. In this manner it was possible to avoid the general reactions in the form of gastro intestinal disturbances, and the reduc-

tion in pain was continuous. This was not possible when the injections were given at intervals of three or four days. The author administered the cobra toxin always after radium or roentgen treatment, never simultaneously with it. He points out that cobra toxin is now also used for the therapy of cancer and mentions some of the investigators in this field. He admits that he himself never observed an objective improvement of the local gynecologic condition. Nevertheless he thinks that in the future snake venoms might be of greater importance in their direct action on cancer tissues than in their analgesic action.

**Use of Artificial Gastric Juice in Compound Fractures**—Yanovskiy states that debridement and primary closure of lacerated traumatic lesions is permissible in the first six hours only. After this period, in order to be efficacious, the treatment must be combined with the use of antiseptics. In 1930 Yaure and Busurina reported experiments in which they demonstrated the markedly bactericidal action of artificial gastric juice against a number of pathogenic bacteria in vitro. They showed that the bactericidal action of the artificial gastric juice depended on the combined action of its components, hydrochloric acid and pepsin and not primarily on the concentration of the hydrochloric acid. Besides the bactericidal action the juice aids in the autolysis and sloughing of the devitalized tissues. The author treated thirty patients having compound fracture of the bones by debridement of the wound, irrigation of the wound with artificial gastric juice and primary suture of the skin. Of the thirty injuries fifteen were fractures of the tibia, four of the femur, five of the forearm, four of the humerus and one of a phalanx; the remaining injury was a compound dislocation of the hip. More than half of the patients were treated from twelve to twenty-four hours after the injury. Twenty-six were healed by primary intention and four developed an infection. The author concludes that the use of the artificial gastric juice will permit of extending the indications for the primary closure of lacerated wounds. The artificial gastric juice was prepared according to the following formula: diluted hydrochloric acid 18 parts, pepsin 20, distilled water 1,000, glycerin 5.

Treatment of Varices with Injection of Larger Amounts of Highly Concentrated Sugar Solution and Ligature of Vein F Sjøgaard—p 99

Glycolytic Enzymes in Spinal Fluid A Faurbye—p 110

**Anemia in Cancer of Stomach**—Mogensen states that in seventy-five cases of gastric cancer the average percentage of hemoglobin was 72.8. In 31 per cent of the cases there was no anemia and he concludes that the presence of a normal percentage of hemoglobin is without significance in the diagnosis of cancer of the stomach. No connection existed between achylia and tendency to anemia or between the degree of occult hemorrhage and anemia and the anemia was independent of age, sex and duration of the disease. Undernutrition and cessation of the antianemic function of the stomach are regarded as the main causes of the anemia. Two cases of cancer of the stomach with marked anemia as the chief symptom are described: one with a hypochromic and microcytic anemia which responded favorably to treatment with iron and the other with a hyperchromic megalocytic anemia which reacted well to treatment with liver and stomach. The importance is stressed of active treatment of the anemia in cancer of the stomach by (1) the best possible nutrition both quantitatively and qualitatively and (2) direct antianemic treatment with iron or with liver and stomach or both, the choice being based on the hematologic picture.

Course of Pulmonary Tuberculosis in Children L Salomonsen and H Trættemberg—p 194

**Metabolism in Lipoidosis**—A woman aged 31, had multiple xanthomas on the fingers, elbows and one heel. Examination of her family revealed hereditary hypercholesterolemia, apparently handed down by both sexes as a dominant factor and expressed in part by xanthoma formation, in part only by chemically demonstrable changes in the blood. The total cholesterol and fat in the patient's blood were increased to about 250 per cent, the phosphatide to from 150 to 200 per cent. Chemical examination of one xanthoma showed 24.9 per cent of cholesterol, 20.4 of fat and 0.26 of acid phosphatide phosphorus in the dry substance. The tolerance test with cholesterol caused only a weak rise in cholesterol values. An attempt to withhold cholesterol caused no noticeable change in the cholesterol values in the blood. The amount of cholesterol in the bile and the feces was normal. Ræder concludes that the condition in his case is due not to a defect in elimination but to an unexplained defect in regulation. He says that, while there are several forms of disturbances in metabolism which may lead to xanthoma formation, this case belongs to a relatively well recognized type, a familial juvenile form. Many patients with the disorder die suddenly with the picture of heart disease and lipid deposits are found in the heart. A therapy to lower the lipid level in the blood is thus called for. Roentgen irradiation of the hypophysis region proved ineffective in the case described. At present the only treatment available is treatment with a cholesterol-free diet.

**Still's Disease**—Hajks says that in 1929 slowly increasing rigidity and swelling in the articulations of the extremities and rigidity of the spinal column, especially in the cervical portion began in a girl, aged 14. From 1930 through 1932 several periods of intermittent fever occurred, lasting from two to six weeks, with enlargement of the spleen and lymphatic glands, periosteal nodes in the wrists and elbows, kneecaps and ankles and in the middle of the forehead, pronounced muscular atrophy and a poor general condition. Physical development was greatly retarded, psychic development was about normal. The skin was gray and pale with yellowish brown pigmentation on the cheeks. There was onychogryposis of the nails of both big toes. Menstruation had not begun. Roentgen examination showed marked deficiency in calcification in the knee and wrist joints. Sixteen injections of fibrolysin were without effect on the condition. Since 1932 there has been no marked fever period and the condition seems about stationary. The clinical picture is thought to conform with that in Still's disease beginning in the first decade of life.

**Acute Pancreatic Necrosis**—Grønn says that his first case of traumatic isolated pancreatic lesion was the only one of its kind in 6,754 necropsies and that only five instances of traumatic pancreatic necrosis have been reported previously in Norway. The trauma is believed to have caused a primary crushing of the pancreatic tissue or pancreatic hemorrhages causing partial necrosis in either event leading to activation of trypsinogen into trypsin and to a weakening of the pancreatic tissue, resulting in autodigestion of the pancreas. In the second case, hemophilia, spontaneous hemorrhage in the pancreas activated the pancreatic enzymes and produced an acute hemorrhagic pancreatic necrosis developed after high strangulation of the afferent loop of the jejunum following resection of the stomach. The contents of the distended duodenum were forced into the pancreas through the pancreatic duct and activated the trypsinogen, with resulting autodigestion of the pancreas. The cause of death was autointoxication, mainly attributable to the high ileus but in part due also to the secondary pancreatic necrosis.

## THE TREATMENT OF EARLY SYPHILIS

OLIVER S ORMSBY, M D

CHICAGO

The treatment of early syphilis is now fixed on a firmer foundation than at any previous time in history. The standard method followed in the major clinics in this country was developed over a period of years of trial of diverse methods in many centers. Before this is discussed in detail, a brief review of the evolution of the subject of treatment will not be amiss.

Before the discovery of arsphenamine in 1910, mercury and potassium iodide were the chief weapons of defense and attack. These drugs accomplished results by aiding nature in building up its defenses to combat the invading infection. That they accomplished much there is no doubt, but that more efficient weapons were demanded is equally true.

Mercury was used by injection, by inunction and by mouth. For those of us who had some years of experience with these preparations alone, it is interesting to recall the numerous untoward effects that occurred. Even fatal results sometimes followed the employment of gray oil and the mercurous chloride by injection. These facts cause us to view similar happenings with the modern drugs with less criticism. On the other hand, we can also recall the good clinical results achieved, which sometimes were striking, in the late benign nodular and ulcerative cases.

Before 1905 the diagnosis depended entirely on clinical experience and the termination of treatment (if ever) also was predicated on the world experience of syphilologists.

The discovery of *Spirochaeta pallida* in 1905 made a positive diagnosis possible during the first few days of the existence of a lesion, which if untreated would in time develop into a clinically recognizable chancre. The elaboration of the Wassermann reaction some years later, together with precipitation tests, added other valuable means for the early detection of the disease. Its early recognition and institution of treatment was considered important but less so than at present on account of the slower action of the drugs then employed. There were some dissenters, however, who believed that treatment should be delayed until the so-called secondary manifestations appeared. By this time there has been established a certain amount of immunity, which is of value in protecting the patient from some of the more severe ravages of the disease. Removal of this natural protection by early treatment with inadequate amounts of arsphenamine has often been followed by more serious developments that would probably have been avoided without such treatment. This natural immunity is further exemplified by the

large number of cases of latent syphilis seen in every large clinic, in many of which the latency is permanent. This fact, however, does not relieve one of the responsibility of treating latent syphilis for several reasons. First, these patients are a menace to others to whom they may transmit the disease and if of the female sex, may transmit the condition to their offspring. And, second, efficient treatment greatly reduces the chance of development of the more serious forms of the disease in the viscera and nervous system.

It might be thought that, could an efficient method of treatment of early syphilis be developed and carried out whereby the major portion of this class could be cured, the late and more serious effects would be eliminated, i. e., visceral and neurosyphilis would be avoided. This fortunate result cannot happen for the reason that the large latent class previously mentioned pass the early stage unnoticed. They have had either mild or no appreciable signs of the disease in its early stage and it was therefore not recognized and this group will continue to furnish endless examples of the late stages.

In undertaking the treatment of early syphilis, one should bear in mind certain facts regarding its course. The natural tendency of the disease untreated is toward spontaneous cure. This is evidenced by the period of latency established by the production of immunizing substances, which hold the activity of the organisms in abeyance either temporarily or permanently. Interference with the establishment of this partial or complete immunity by inefficient treatment may advance the late serious developments in the central nervous system and viscera appreciably.

The development of immunity and the occurrence of spontaneous cure in a certain percentage of cases of untreated syphilis were admirably shown by Bruusgaard<sup>1</sup>. In the Oslo clinic where the standard treatment of the time, consisting of mercury and potassium iodide, was considered of little or no value, 2,181 patients with primary or so-called secondary syphilis passed through, between the years 1891 and 1910. Fifteen years later, Bruusgaard reexamined by modern methods 309 of this number and discovered the cause of death in 164 others, in forty of whom necropsies were performed.

In this group neurosyphilis developed in 9.5 per cent, cardiovascular syphilis in 12.8 per cent, benign late syphilis in 12.2 per cent, latent syphilis (no clinical signs, positive Wassermann reaction) in 14.1 per cent, spontaneous cure in 27.9 per cent, and death resulted from syphilis other than of the cardiovascular or central nervous system in 0.8 per cent and from other causes in 22.6 per cent. These reliable statistics reveal the interesting fact that more than 25 per cent of the

<sup>1</sup> Bruusgaard cited in Moore, p. 23.

patients made a spontaneous recovery and that approximately 64 per cent were individually unharmed by the disease

The treatment of latent, visceral and late benign syphilis, which includes the late lesions of the skin and osseous system and syphilis in pregnancy, is a major aspect of the syphilis problem but will not be fully discussed here. The development of an efficient method of treatment of early syphilis revolves around arsphenamine and bismuth compounds, which can best be brought out by some historical data.

Beginning in October 1910, my associates and I treated a group of cases with arsphenamine furnished by Dr Simon Flexner of the Rockefeller Institute at the suggestion of Capt H J Nichols of the U S Army. The results were recorded in THE JOURNAL in February 1911<sup>2</sup>. The drug was then given subcutaneously, and a single injection was expected to be sufficient to eradicate the disease. The injections were painful and not devoid of danger. Somewhat later the drug was administered by intramuscular injection as an emulsion in oil. This method was very efficient therapeutically but was not infrequently accompanied by untoward results both locally and constitutionally. Very shortly afterward the intravenous method of administration was developed and universally adopted. The hope that a single injection would be sufficient to eradicate the disorder was soon dissipated and, as time passed, the number of injections considered adequate has been greatly increased.

In our comparatively early work we found that administration of the drug in gradually ascending dosage was inefficient, but we still adhere to a small initial dose. We also determined that more efficient response was had by giving the first three injections during the first week rather than making a five or seven day interval from the beginning.

Experience soon revealed that arsphenamine alone was inadequate, so its use was combined with that of mercury, and this combined method of treatment was universally adopted. Bismuth appeared in about 1920 and its use and the development of new preparations was energetically prosecuted, especially by French investigators. In a comparatively short time its great value became evident, and its use supplanted to quite an extent that of mercury. Numerous valuable preparations of bismuth have been elaborated. They are divided into three groups: water soluble, oil soluble and insoluble. We have employed an insoluble salt from the beginning as a routine procedure.

When it became established that the combined use of these heavy metals was the best procedure, numerous plans were devised and tested. In the major portion the treatment was divided into courses, each consisting of a certain number of injections of arsphenamine followed by a given number of injections of mercury (early) or a bismuth compound (later). Such courses were separated by a period of rest. Such a plan was used in the extensive treatment required during the World War. Five courses were generally recommended during the first two years.

This method was widely used for some time until it became evident that numerous clinical and serologic relapses developed during the resting periods, which fact led to the continuous method now generally employed. Even with this method a moderate number of resistant cases are encountered, both clinically and serologically, but fortunately the number is small. The

continuous method was first suggested and carried out in Europe by Almkvist<sup>3</sup> and in this country by Keidel,<sup>4</sup> though the latter employed this method several years before making the report. Much study, both experimental and clinical, has been made to determine the relative value of the various arsphenamines. I believe that arsphenamine is the treatment of choice, but its employment requires more time and skill in its administration, and untoward results are more likely to occur. Neoarsphenamine practically fulfils all the necessary requirements and its simplicity of preparation for injection and administration commends it to the average practitioner. Sulfarsphenamine proved to be toxic and is employed only when intravenous injections are not possible. Silver arsphenamine is very valuable, both clinically and serologically, but when given in large amounts is not unattended with danger (pigmentation). Spiegel<sup>5</sup> found that if a maximum dosage of 8 Gm is not exceeded this deleterious effect may be avoided. Bismarsen is a combination of arsphenamine and bismuth and may be used in exceptional cases.

In this country it now is the consensus that eighteen months' continuous treatment is adequate to eradicate the disease in most instances. A minimum of twenty injections of arsphenamine is required in this period.

A rule that I have followed from the beginning requires an examination of the patient preliminary to the institution of treatment. This includes an examination of the heart, the eyes and the urine. A record of these observations becomes valuable for future reference as well as to detect contraindications for the use of arsphenamines.

With the efficient drugs available, treatment should be instituted at the earliest possible moment, i e, when a diagnosis has been made either by the demonstration of *Spirochaeta pallida* or by a positive Wassermann reaction or definite clinical evidence. If started early before the natural defense mechanism has had time to function, the necessity of continuous vigorous treatment is imperative. By any of the modern schemes of treatment the Wassermann reaction becomes negative and all signs of the disease have disappeared by the end of the first course. If at this time a lapse of treatment occurs, either voluntarily or through some neglect by the patient himself, disastrous developments may occur such as neurorecurrences or other relapses, so that it is of the utmost importance that no interruption in the treatment be allowed under any circumstances. If the Wassermann reaction remains positive after the first period in spite of continuous treatment or if a Wassermann relapse occurs, examination of the spinal fluid is indicated.

A comprehensive study of the disease with results of various methods of treatment was carried out in this country under the direction of the U S Public Health Service and five cooperating university clinics.<sup>6</sup> The material studied included the records of 75,000 cases of syphilis, of which 3,244 were early cases. The observations in this survey are of the utmost importance and the recommendations for the management of the disease in all its phases and situations are worthy of adoption. These statistics reveal the fact that in early syphilis the continuous method of treatment

achieved satisfactory end results in 79.7 per cent of cases, whereas similar results occurred in 65 per cent with the intermittent method (rest intervals).

A schematic outline of treatment published by Moore<sup>7</sup> in collaboration with the university group may be considered a standard method of treatment for early syphilis. This scheme calls for alternate periods of arsphenamine and bismuth compound for seventy weeks with no rest intervals. The total injections of arsphenamine are thirty-two and of bismuth thirty-eight. There are essentially five courses each of arsphenamine and bismuth. Each course of arsphenamine includes six weekly injections with the exception of the first at which time eight are given the first three of which are at intervals of five days. Each course of arsphenamine is followed by one of bismuth. The bismuth courses increase progressively the number of injections in the respective courses being four in the first course six in the second eight in the third and ten each in the fourth and fifth.

Potassium iodide is given with the bismuth in the first series of injections. If mercurial ointment is substituted for bismuth potassium iodide is given with it in each course. In seronegative primaries in which a positive Wassermann reaction does not develop treatment may be suspended at the end of the fourth course. A spinal fluid examination is recommended at the end of the second course. During the year of observation after the cessation of treatment several blood Wassermann examinations are made and at the end of the year a complete neurologic examination including the spinal fluid and complete physical examination with particular reference to the cardiovascular system. Thereafter there should be an annual physical examination together with a blood Wassermann test.

In the syphilis clinic of the Central Free Dispensary where the work is carried out under the supervision of Dr Skolnik the continuous method of treatment has been in operation for six years. In this clinic neoarsphenamine is used and five courses are given covering a period of twenty-seven months. Here the first three injections are given in the first week then three at intervals of five days then four combined injections of neoarsphenamine and bismuth at weekly intervals this being followed by alternating series of bismuth and neoarsphenamine separately throughout the following courses. Using the bismuth early in the first course appears justifiable by the results obtained. It is interesting to note here that in Moore's scheme<sup>8</sup> published in his work on syphilis in 1933 he advised bismuth simultaneously with the first four doses of arsphenamine.

The object of using bismuth with the first few injections is to increase the natural defense forces which have been held in abeyance by the arsphenamine.

A summary of the treatment in 124 cases of early syphilis in our dispensary clinic, furnished by Drs Skolnik and Webster showed one mucocutaneous relapse eight serologic relapses and one neurorecurrence. The patient with the neurorecurrence received forty-one neoarsphenamine and seventy-five bismuth injections in thirty-three months. The Wassermann reaction of the spinal fluid at this time was positive. All other tests were negative.

There were eleven gastro-intestinal one Jarisch-Herxheimer and dermatitis (one of which was of fixed

type) and three jaundice reactions. A complete report of the results of treatment in all its phases is in preparation and will be made soon.<sup>9</sup>

The treatment of early syphilis in pregnancy is that of the nonpregnant if instituted early, i.e., previous to the third to fifth month. This includes alternating courses of arsphenamine and bismuth without interruption. If instituted later, weekly injections of arsphenamine alone are recommended until the termination of pregnancy.

The treatment of early acquired syphilis in children is identical with that of adults, the dosage being modified to fit the weight. If the intravenous method is not practicable, sulfarsphenamine may be used by the intramuscular route.

The treatment of early syphilis in the elderly should be sufficiently energetic to protect from recurrences and the later more serious developments but does not require as large dosage of arsphenamine or the rigid adherence to the regimen suggested in younger patients for so long a period.

#### REACTIONS, LOCAL AND GENERAL, REQUIRING ATTENTION

Occasionally during an injection of arsphenamine pain is complained of extending up the arm to the shoulder. This is usually due to overalkalization of the drug and requires no further treatment than attention to this matter. Thrombosis which is due to the same cause, may be avoided in a similar manner. General reactions are much more important.

The Jarisch-Herxheimer reaction does not cause serious damage in early syphilis but may do so in the later stages. This reaction is due to the rapid destruction of a large number of spirochetes and to the liberation and absorption of their proteins. A constitutional reaction consists in elevation of temperature preceded by a chill, malaise and general aching. Focal symptoms consist in increased activity in affected areas. An early eruption barely visible becomes marked. These symptoms soon subside and are of no particular moment. When however, there is activity of the process in the larynx, heart or brain serious accidents might occur through activation of lesions in these situations. To prevent this reaction in early cases, the first dose of arsphenamine should be small. In late cases treatment with arsphenamine if used at all, should be preceded by courses of mercury, potassium iodide and bismuth.

**Acid Arsphenamine**—If through error arsphenamine is given without being alkalinized, serious results occur. If the full dose is injected, a fatal result occurs immediately. If during an injection a patient coughs, the injection should be stopped immediately and examination made of the arsphenamine to see if it has been properly prepared. If much of the drug is given there occurs severe coughing, oppression in the chest, pain in the back, pallor, syncope, circulatory collapse and immediate death. To combat these symptoms, if there is time, epinephrine is given by subcutaneous injection and oxygen by inhalation and the patient is kept warm in bed.

**Ether Odor**—Occasionally during the injection the patient complains of smelling ether. This phenomenon occurs within a few seconds after the beginning of the injection. It is due to action on the nasal mucosa of the arsenic itself or of ether used in its manufacture. This is unimportant and requires no treatment.

8 Moore J. E. The Modern Treatment of Syphilis. Springfield Ill. Charles C. Thomas Publisher 1933 p. 201.

9 Skolnik E. A. and Webster J. R. to be published.

**Gastro-Intestinal Reactions**—From 25 to 40 per cent of the patients receiving the arsphenamines have some gastro-intestinal reaction. This includes malaise, headache, nausea, vomiting and diarrhea, beginning from four to twelve hours after the injection. It lasts from a few hours to several days. It may be due to impure water, underalkalization of the arsphenamine, too rapid injection, dietary errors and constipation. When these conditions are corrected there is no reason why treatment should not be pursued with the arsphenamine.

**Nitritoid Crisis**—This occurs during the injection and is expressed by a feeling of heat, palpitation, oppression in the chest, suffusion of the conjunctivae, flushing of the face, coughing, vomiting, sometimes diarrhea, pain in the back, and falling of the blood pressure. Edema may be severe and occur on the face, lips, tongue and glottis, as well as on the extremities. Urticaria may supervene, and pain in the gums and teeth may be present. A severe syncope sometimes happens and the pulse becomes thready. While the symptoms appear alarming they are not important, as they pass off in from fifteen minutes to an hour. This reaction is due to physical causes and not infrequently to the rapidity of the injection. It has been termed speed shock. Certain batches of the arsphenamine seem more prone to induce it than others. Treatment consists in the immediate injection of 10 drops of a 1:1,000 solution of epinephrine intramuscularly. If this reaction is recurrent, 5 minims (0.3 cc) of epinephrine may be given before each injection. Stokes recommends ephedrine in the dosage of 50 mg a day during the arsphenamine period and the administration of from  $\frac{1}{60}$  to  $\frac{1}{50}$  grain (1 to 2 mg) of atropine before the injection.

**Shock Reactions**—These occur from the injection itself and resemble surgical shock and are treated in the same manner. The condition comes on a few hours after the injection and the hypothesis is given that it is due to acute adrenal injury. Treatment consists in application of heat in bed and the slow administration of 2 or 3 liters of a 10 to 15 per cent dextrose solution or a similar amount of physiologic solution of sodium chloride. Epinephrine has no effect on this condition.

**Cutaneous Eruptions**—Several of these are important. They include urticaria, various erythemas, herpes simplex and zoster, fixed eruptions, purpura and varying grades of dermatitis, including papular, papulovesicular, vesicular and exfoliative. Only those requiring special attention will be discussed. In the blood dyscrasias shown by purpura, further use of arsphenamine is contraindicated. The same is true in the sensitization type of exfoliative dermatitis. In this type even small doses given long after the dermatitis is cleared up will provoke a recurrence, as has been demonstrated by Moore and Robinson. Severe dermatitis exfoliativa sometimes follows one or more mild attacks of cutaneous disturbance, and it is therefore necessary to be on the alert and discover these mild reactions. In most instances, however, the severe attack develops without previous warning. The treatment of general exfoliative dermatitis with sodium thiosulfate popularized in this country by McBride and Dennie,<sup>10</sup> is accepted as of value by most workers, a notable exception being Moore<sup>11</sup> who after several years of experience found the drug of no value. In my own work I employ injec-

tions of dextrose recommended by Shaffer,<sup>12</sup> particularly those cases accompanied by edema, in conjunction with sodium thiosulfate. The drugs are given on alternate days, the sodium thiosulfate in the dosage of 1 Gm and the dextrose in the dosage of 20 cc of a 50 per cent solution.

**Argyria from Silver Arsphenamine**—This drug is very efficient but is not devoid of danger. Spiegel found that a maximum of 8 Gm is the limit of safety, and if this is observed pigmentation probably will not follow.

**Polycymitis**—Fortunately, these cases are rare. My personal experience consists in one example, and this ran a long continuous course with poor recovery.

**Hemorrhagic Encephalitis**—This is a grave and, fortunately, rare complication. This condition develops ordinarily after the second, third or fourth injection. The symptoms begin two or three days after the last injection and consist of severe headache, nervousness, apprehension, apathy, mental confusion, convulsions, urinary and fecal incontinence, dilated pupils, cyanosis, the development of a comatose condition and death within twenty-four to forty-eight hours. Schamberg and Wright recommend the following treatment. With the patient remaining in bed a dorsal puncture is done, removing 50 cc of fluid, and venesection, removing from 50 to 100 cc of blood, followed by a purge, large doses of sodium bicarbonate, subcutaneous injections of 5 minims (0.3 cc) of 1:1,000 solution of epinephrine every four hours and oxygen inhalations.

**Postarsphenamine Jaundice**—This complication is not uncommon and it is variable as to degree, from a simple symptomless icterus to an acute fatal yellow atrophy. All grades between the two are seen. In this brief paper it is not possible to discuss the subject thoroughly. By different authorities its cause is attributed to three factors: (1) a toxic action of the drug on the liver cells, (2) syphilis and (3) an intercurrent epidemic disease. Moore is of the opinion, with others, that in the various cases a combination of all these factors is the correct hypothesis. The further use of arsphenamine is temporarily abandoned. The treatment of the liver symptoms is largely symptomatic, rest in bed and a bland soft diet, together with saline cathartics. Moore recommends daily injections of calcium gluconate and Schamberg and Brown recommend calcium thiosulfate. In early syphilis on the suspension of arsphenamine and the subsidence of acute symptoms, bismuth and potassium iodide are continued. Arsphenamine may be resumed several weeks after the icterus is cleared up. In the beginning the dosage should be small, 0.05 Gm. That some remote result may occur is possible, and O'Leary<sup>13</sup> has already recorded cirrhosis of the liver in such patients several years after the original attack of arsphenamine icterus.

#### SUMMARY AND CONCLUSIONS

With modern methods of treatment, early syphilis can be eradicated in the majority of cases.

Continuous treatment with no rest periods gives the best results.

Alternate courses of arsphenamine and bismuth are recommended covering a period of at least eighteen months and employing a minimum of twenty injections of old arsphenamine or its equivalent with other arsphenamines.

<sup>13</sup> O'Leary cited by Moore p. 102.

The Wassermann reaction is usually reversed by the end of the first period and should remain so permanently. The early reversal of this reaction indicates proper progress of treatment, but by no means does it relieve the physician of carrying out the outlined schedule.

An adequate amount of arsphenamine is absolutely essential and nothing save intolerance, indicated in the body of this paper, should reduce this. A standardized method of treatment for large numbers of patients is justifiable for the reason that this early group includes chiefly young, otherwise healthy, patients who tolerate much treatment with safety, and also because it is at this time that such treatment offers the best chance for eradication of the disease.

## THE TREATMENT OF PERNICIOUS ANEMIA WITH AUTOLYZED LIVER CONCENTRATE

THEODORE G. KLUMPP, MD  
NEW HAVEN, CONN.

In 1931 Reimann<sup>1</sup> noted that when fresh liver was digested in normal human gastric juice its antianemic potency in cases of pernicious anemia was enhanced. This was corroborated by Helmer, Fouts and Zervas<sup>2</sup>. Walden and Clowes<sup>3</sup> reported a similar potentiation of liver and liver extract-Lilly (N. N. R.) when these were incubated with fresh hog gastric tissue. They found that the effectiveness of liver and liver extract was increased three to four fold and that this was appreciably greater than could be accounted for by the simple additive effect of the liver or liver extract and

Chart 1—As 25 of autolyzed liver concentrate. A maximal reticulocyte response is obtained when 25 Gm daily is administered.

gastric tissue. The clinical usefulness of the product developed by Walden and Clowes was established by Fouts and Zervas<sup>4</sup>.

\* Doses of parenteral and oral liver extracts expressed in grams of liver from which the material was derived; ventriculin in grams of desiccated material taken.

to thirteen patients with pernicious anemia, the authors concluded<sup>6</sup> that "the oral dosage requirement of autolyzed liver approached the intramuscular requirement of other liver preparations." That antianemic potency might be influenced by autolysis was further suggested by the observations of Wills.<sup>7</sup> She found that whereas ordinary yeast was inert in treating cases of tropical macrocytic anemia, autolyzed yeast equaled liver in its efficacy. Subsequently Strauss and Castle<sup>8</sup> were able to produce typical reticulocyte responses and remissions in addisonian anemia after an autolyzed yeast preparation had been incubated with normal gastric juice.

On the other hand, Castle and Strauss<sup>9</sup> were not able to substantiate the claims for the potency of autolyzed liver and autolyzed liver concentrates made by McEllroy and Herron<sup>6</sup>. A threefold gain in potency could not be demonstrated and it was shown that concentrates of autolyzed liver were less active than the amounts of liver from which they were derived. With these results, the observations recorded in this report are in complete agreement.

Nevertheless the question still remains whether autolyzed liver concentrate is a useful preparation for the treatment of pernicious anemia and also the important question whether the concentrate of autolyzed liver, which is essentially a liver extract, is more or less potent than other extracts prepared without preliminary autolysis. Data bearing on these considerations are presented in this report.

#### CLINICAL DATA

The therapeutic potency of autolyzed liver concentrate-Squibb (N N R)<sup>10</sup> has been studied for a period of two years in the wards and in the hematology clinic of the New Haven Hospital.

**Initial Treatment**—The blood response to the administration of autolyzed liver concentrate in a case of pernicious anemia is illustrated in chart 1. The preliminary submaximal test of gastrectomized pig's liver,<sup>11</sup> irrelevant to the purpose of this report, does not according to the principles of Minot<sup>12</sup>

weighed, of autolyzed liver concentrate provoked a reticulocyte peak which was slightly higher than standard<sup>14</sup> for adequate therapy. That this was a maximal response was further verified by the absence of a sec-

Chart 3—Studies on the potency of autolyzed liver concentrate in a patient in two relapses

ondary reticulocytosis when 30 Gm. daily of oral liver extract-Lilly derived from 300 Gm. of liver was administered.

The experiment graphically outlined in chart 2 indicates according to the principles formulated by Minot<sup>12</sup> and by Dameshek and Castle<sup>13</sup> that autolyzed liver concentrate derived from 100 Gm. of liver is more potent than liver extract-Lilly derived from the same amount of liver. The third reticulocyte peak obtained when 285 Gm. of autolyzed liver concentrate was administered, suggests that 143 Gm. of autolyzed liver concentrate was less than the maximal dose.

The results of blood studies of a patient in two relapses are given in chart 3. On the first admission the patient received 8 teaspoonfuls daily of autolyzed liver concentrate as a result of which a reticulocyte level of 33 per cent was attained on the eighth day of treatment. For the initial counts averaging 0.76 million red cells per cubic millimeter, this peak is lower than that expected according to the averages of Riddle<sup>14</sup>. This suggests that the dose of autolyzed liver concentrate might have been submaximal. On the other hand Bethel<sup>15</sup> has shown that in some instances in which a more sustained reticulocyte response is obtained the maximal reticulocyte percentage is usually appreciably less than would have been expected on the basis of the initial red blood cell count. To provide a quantitative basis for comparing these curves he devised a method of measuring the total reticulocyte response and constructed a formula for the expected response. In the case under discussion the duration of the reticulocytosis was twenty-one days. By means of planimeter measurements made according to the method of Bethel, the area of the reticulocyte response was 100.1 sq. cm. This is appreciably better than the theoretical expected figure for adequate treatment, which is 75 sq. cm. for

Chart 2—Assay of autolyzed liver concentrate. The reticulocyte curves indicate that the product is more potent than liver extract-Lilly and that the dose necessary to cause a maximal response is greater than 143 Gm. daily.

and of Dameshek and Castle<sup>13</sup> validate the subsequent assay of autolyzed liver concentrate. It is to be noted that daily administration of 285 Gm., accurately

oral liver and 97 sq cm for ventriculin. Furthermore, the gain of 284 million red blood cells in approximately one month was greater than the average increase of 248 million recorded by Minot and Murphy<sup>16</sup> for their cases starting at similar levels. From these facts it seems highly probable that the therapy had been maximal.

In the second relapse the administration of autolyzed liver concentrate derived from 100 Gm of liver provoked a greater reticulocytosis than resulted from liver extract-Lilly obtained from the same amount of fresh liver. A third increase in the percentage of reticulocytes occurred when autolyzed liver concentrate from 150 Gm of liver was given. The significance of the small peak noted on the third day after the administration of autolyzed liver derived from 200 Gm of liver is uncertain. The experiments in this case indicate again that autolyzed liver concentrate is more effective than liver extract-Lilly and that the maximal dose of the former lies between 21.5 Gm and 28.5 Gm, or the amount derived from between 150 and 200 Gm of liver.

The gain in red blood cells following initial treatment with autolyzed liver concentrate in two cases of pernicious anemia in relapse is delineated in chart 4.

Chart 4—The gain in red blood cells following initial treatment with autolyzed liver concentrate in two cases of pernicious anemia in relapse.

**Maintenance Treatment**—The results of the maintenance treatment of patients with addisonian anemia are summarized in the accompanying table. In many of the cases it was possible to introduce control periods in which other forms of therapy of recognized efficacy were administered.

After changing from one treatment to another, the blood counts for a period of three weeks were discarded in order to allow for the carry-over effect of storage of active material. From the table it is evident that maintenance of the red blood count with autolyzed liver concentrate is on the whole satisfactory as compared with other types of treatment. It is noteworthy that the mean maintenance level of the red blood cell counts for all forms of treatment is slightly lower than the values that have been emphasized as the goal of adequate maintenance treatment. In our experience this is due in most instances to spontaneous fluctuations, which are not influenced by any therapy and occur in many patients with pernicious anemia. Innumerable attempts have been made to interrupt the course of these spontaneous variations by the exhibition of massive doses of parenteral liver extract—as much as the amount derived

from 700 Gm of liver weekly—without success. In other instances, specific therapy has been stopped for periods as long as six months without essential change in the average level of the red blood cell count or in the

Chart 5—The effect of intermittent treatment with autolyzed liver concentrate on the red blood cell count of a patient with pernicious anemia.

symptoms. That this is not true for all cases of pernicious anemia is strikingly illustrated in chart 5. In this case, which has particular value in demonstrating the efficacy of treatment, the red blood count and symptoms followed very closely the amount of autolyzed liver concentrate taken. It is important, then, in evaluating any form of maintenance treatment that the observations should extend over a long period of time, include a series of patients and, if possible, be controlled by other types of therapy. An example of extended maintenance with the form of treatment under consideration is given in chart 6.

The average maintenance dose of autolyzed liver concentrate was found to be 3 level teaspoonfuls daily with a range of from 1 to 8 teaspoonfuls. In general, doses larger than average were necessary for the aged and those with extensive neurologic disturbances. In some

Chart 6—Maintenance treatment of a case of pernicious anemia with autolyzed liver concentrate.

of these cases, oral therapy in any form was economically unpractical. In a number of cases, repeated allergic reactions to the parenteral administration of liver extract made oral treatment obligatory.

The effect of treatment with autolyzed liver concentrate on the symptoms of pernicious anemia, initially and thereafter, was commensurate with that obtained from other forms of therapy.

#### SUMMARY

1. Autolyzed liver concentrate is effective in the initial and maintenance treatment of addisonian anemia.
2. Autolyzed liver concentrate is more potent than liver extract-Lilly derived from the same amounts of liver.

3 In the initial treatment of pernicious anemia, maximal effects have been obtained from a daily dose of autolyzed liver concentrate derived from between 150 and 200 Gm of liver

4 For maintenance treatment a dose of from 1 to 8 teaspoonfuls daily, on the average 3 teaspoonfuls, has been found adequate

## THE SUBCUTANEOUS INJECTION OF ALCOHOL FOR PRURITUS ANI

BENJAMIN HASKELL, MD

AND

CLARENCE D SMITH, MD

PHILADELPHIA

In the majority of cases of pruritus ani, the cause of the distressing itching is found to be associated with some variety of local lesion and the treatment is determined by the specific nature of this cause. There are, however, a considerable number of cases of intractable, severe pruritus in which no causative factor can be discovered and which have been variously designated as "essential" or "idiopathic." The extremely varied types of treatment suggested and the large number of remedies employed are evidence of the difficulties in securing relief in these cases. The use of alcohol by subcutaneous injection first introduced by Stone<sup>1</sup> and later employed by Buie<sup>2</sup> in a modified form, has been found to be a particularly effective means of treatment. The employment of this method by a somewhat modified technic in a series of twenty-two patients observed for a period of a year or more is presented in this report.

The clinical features presented by this group of patients were more or less characteristic. The itching has usually been of long duration and fairly constant. It is often intense, especially at night. Sleep is inadequate and, with the inability to secure sufficient rest, the general health may be impaired. Scratching may be so marked during sleep that the skin bleeds. Many and varied remedies have been tried with only partial or temporary relief. It is because of the great distress these patients suffer that a more radical measure, such as the method to be described, becomes necessary. Either no pathologic change was found in the terminal colon or rectum or, when such had been present, appropriate measures were undertaken for their removal without appreciable relief from the itching. No etiologic factor, either general or local, could be found to account for the intractable pruritus.

As a rule, both gross and microscopic changes were found on examination of the skin about the anus. These changes probably occur as a result of scratching, followed by bacterial invasion of the tissues and, to some extent, from previous treatment. The skin is usually a grayish white and markedly thickened. In some it is tough and of a leathery consistency, in others it is thick and soggy, presenting an appearance described as "parboiled." There may be numerous reddened and excoriated areas and even pustules with excessive secre-

tion and moisture. The microscopic appearance, according to Crawford,<sup>3</sup> is essentially that of a low grade inflammatory process with proliferative changes. He found marked thickening of the surface epithelium with hyperkeratinization, and dilatation of the superficial blood vessels and lymphatics, with extensive infiltration, usually of small lymphocytes. The deeper layer of the cutis shows extensive fibrosis, while the upper layer may be edematous. The cutaneous nerves show no evidence of involvement. These observations are in agreement with those reported by Montgomery.<sup>4</sup>

An analysis of the methods of treatment that have been successful in relieving these cases of intractable pruritus indicates that they all attempt to accomplish their effect either by severance, anesthesia or destruction of the peripheral sensory nerve filaments immediately beneath the involved skin. The effect of alcohol in destroying nerve fibers with which it comes in contact is well known. In our opinion the most effective method has been that suggested by Buie. Briefly, this method may be described as follows. Under sacral anesthesia, with the patient prepared as for the ordinary rectal operation, 40 per cent alcohol is injected subcutaneously, exactly as a solution is used for local infiltrative anesthesia. Careful and detailed postoperative care is administered while the patient remains in the hospital for two or three weeks and under treatment for a period up to two months. Although sloughing of some of the superficial tissues occurs in a large proportion of cases, it may be kept down to a small area without subsequent ill effect. While results have been extremely good, there are certain inherent difficulties in carrying out this procedure. Chief among these has been the difficulty in providing from two to three weeks of hospitalization, with what amounts to almost private nursing care, for the majority of patients. With this in mind, we have employed a method, based on both the foregoing technic and that originally suggested by Stone, by which the alcohol is injected in several stages under local anesthesia and without hospitalization.

### METHOD OF TREATMENT

The patient is placed in the Sims position and the perianal area is prepared as for any rectal operation under local anesthesia. Only a segment of perianal skin, either one fourth or one fifth of the entire area, is selected for treatment at one time. Just beyond the outer edge of the involved skin, which can usually be outlined by its appearance, a small wheal is raised by the injection of procaine hydrochloride. Through this wheal, a needle of 20 or 22 gage and from 2 to 3 inches long is passed under the skin and a 2 per cent solution of procaine hydrochloride is injected subcutaneously, as thin a layer of fluid as possible being made, with little or no distention of the skin. In this manner and without withdrawal of the needle, the fan-shaped segment selected is injected from the border of normal skin to the mucocutaneous margin. From 3 to 5 cc of procaine hydrochloride solution is required and it is advisable to inject it under an area slightly greater than that in which the alcohol is placed. The needle is next carried near the outer limits of the anesthetized area, a second syringe is attached and 70 per cent ethyl

alcohol is injected as the needle is withdrawn through the tissues. By moving the needle back and forth, one can distribute the alcohol in such a manner as to distend the skin uniformly and without too much tension. The folded, very irregular, surface of the skin about the anus renders it difficult in many instances to keep the injection at a uniform depth and concentration. The quantity of alcohol used is equal to that of the procaine hydrochloride solution employed in the area. A mild antiseptic dressing is applied and the patient is allowed to return home. If the procaine hydrochloride has been properly placed, very little discomfort is experienced. The patient is advised to carry out adequate cleansing of the area to apply hot saline compresses two or three times daily for several days and to keep a suitable dressing over the area. The same procedure is then repeated at intervals of from four to seven days until the entire perianal skin has been so treated. Depending on the area injected at any one time, from four to six such treatments are necessary requiring a total quantity of from 15 to 20 cc. of alcohol.

Several precautions should be observed in carrying out this plan of treatment. The alcohol must be placed in the relatively loose subcutaneous tissue. If it is injected intradermally a slough is certain to result. Care must be taken also to avoid injecting it deep enough to involve the anal sphincters. In the male, the membranous urethra is not far beneath the skin, and the alcohol must be placed superficial to this structure to avoid serious injury. Too great a quantity should not be injected under a small area. This is especially likely to occur under the creased skin between the folds. Excision of tissue is not to be done at the same time as the injection or an indolent wound will result which may require weeks to heal.

The only complication encountered was some slight sloughing of tissue, which occurred in six of the twenty-two patients treated. This was evident early by the formation of a small abscess associated with the usual signs and discomfort and followed later by a small ulcer with a necrotic base. In only one instance was it larger than the wound which would result from the removal of an external skin tag. Except for the slight discharge, no discomfort was experienced as a rule and satisfactory healing took place in from three to four weeks. No special measures were employed other than those ordinarily used in the treatment of any open wound in this area.

#### SUMMARY OF CASES TREATED

The method as outlined was carried out in twenty-two patients, all of whom were observed for at least one year following the treatment. Of the group thirteen were males and nine were females, with an average age of 43 years. Symptoms had been present for periods varying from six months to seven years, the average duration being two and three-fourths years. In all of them any pathologic condition present at the initial examination which was regarded as a possible cause of the pruritus was removed or corrected as far as possible. The present treatment was not undertaken until after this had been done without relief of symptoms and until after the ordinary measures had failed. As stated before, most cases of anal pruritus will be relieved by simple measures or after the removal of associated pathologic conditions. Alcohol was not injected as a routine as the patients presented themselves but after we felt that we were dealing with an intractable type of itching.

The results have been very satisfactory. Of the twenty-two patients sixteen experienced complete relief from all itching and have remained so for a year or more, four were made comfortable but were not entirely relieved. Occasional slight itching persisted, but it was reported as not being very distressing. Two cases were regarded as failures. Although there was relief for several weeks the itching returned as intensely as before. In one of these, treatment was repeated with the same result. A very striking feature observed in many cases was the improvement in the appearance of the anal skin. Instead of its tough, leathery surface often badly excoriated the skin became soft and smooth closely approximating its normal state. A microscopic study of the skin was not made after treatment. The development of a slough, which occurred in six of the cases, did not influence the ultimate outcome and, in some instances in which

Summary of Cases Treated

it occurred, the results were probably better because of the greater fibrosis. No other complication was encountered.

#### CONCLUSIONS

1 There are a number of patients with severe intractable anal pruritus in which no causative factor can be demonstrated and in whom the employment of ordinary methods of treatment are not effective. The clinical features of this type are more or less characteristic.

2 Seventy per cent alcohol can be injected subcutaneously in such cases, under one segment of perianal skin at a time, and after preliminary anesthesia with an equal amount of procaine hydrochloride, for the purpose of destroying superficial nerve filaments. Hospitalization is not required.

3 Twenty-two patients observed for a year or more were treated by this method. Sixteen secured complete relief, four were made comfortable but not entirely free from itching and two were classed as failures, relief lasting for a short period only.

4 The method is effective when carried out with certain precautions. No serious complications were encountered.

## THE USE OF LARGE VOLUME INTRAVENOUS INJECTIONS

ROBERT K. CUTTER, M.D.  
BERKELEY, CALIF.

The literature on large volume intravenous injections is so voluminous, the statements and recommendations involved in the selection of proper fluid, the dose, the rate of injection, the temperature of the fluid and the cause of reactions are so contradictory that many of the medical profession are greatly confused. The average man under these circumstances would prefer to go according to the usual practice rather than according to what may eventually prove to be the ideal practice. Unfortunately he has no means of knowing what is the usual practice of other than his immediate confreres, who may be just as much at sea as he is. Because of my connection with a laboratory making and distributing intravenous solutions, I am in an unusually advantageous position to learn what is being used in various sections of the country and also to learn what points most often confuse the practicing physician. An attempt is made to give "middle of the road" answers to the questions most frequently asked of our staff. Every statement made (or that could be made) will be in direct disagreement with the thought or writings of some man who has wide experience in this field.

### SOLUTIONS USED IN VARIOUS SECTIONS OF THIS COUNTRY

Table 1 gives the percentage of certain solutions to all solutions used in various localities according to the distribution figures of the Cutter Laboratories. It is subject to certain errors. For instance, the figures largely represent sales to dealers, and the dealers in a particular territory might be heavily stocked in one type of solution at the first of the period and very low in stock at the end of the period, or vice versa. It is

TABLE 1—Distribution of Various Solutions in Different Regions of the United States

Region	Dextrose 5% in Salt Solution	Dextrose 10% in Water	Dextrose 10% in Water	Dextrose 10% in Water	Ringer's (Also Dextrose in Ringer's Solution)	Lactate Ringer's (Hartmann's)	All Other Solutions
Northeast	62%	3%	16%	1%	18%		
Southeast	26%	1%	14%	4%	42%	1%	12%
North midwest	44%	6%	23%	5%	18%	1%	3%
South midwest	31%	5%	35%	7%	18%	4%	
Northwest	43%	9%	24%	11%	11%	2%	
Southwest	14%	4%	24%	38%	18%	2%	
Average	36%	5%	23%	11%	21%	1%	2%

Percentages represent the proportion of a certain type of solution to the total of all types of solutions used in that area. Blank spaces represent less than 0.5 per cent.

not believed, however, that these errors are great. It probably shows the picture more accurately than would figures based on a questionnaire sent to various physicians and hospitals.

The table is interesting in that it shows that preferences differ markedly. For instance, dextrose 5 per cent in physiologic solution of sodium chloride is called for in the Northeast more than four times as frequently as it is in the Southwest.

Dextrose in salt solution seems to be quite generally preferred to dextrose in water. There has been a

definite decline in the use of physiologic solution of sodium chloride and now it remains the most popular choice in only one region—the Southeast.

### PRACTICAL POINTS INVOLVED IN THE USE OF LARGE VOLUME INTRAVENOUS INJECTIONS

Intravenous injection of large quantities of fluids should be used only when simpler methods of administration are inadequate or too slow. On the other hand, this operation has now been so simplified and reactions so common in the past have been so effectively reduced

TABLE 2—Caloric Requirement With and Without Fever

Calories Required 24 Hours			Calories Required 24 Hours		
Weight (Pounds)	Without Fever	With Fever	Weight (Pounds)	Without Fever	With Fever
10	150	180	100	1500	1800

20	300	360	120	1800	2160
25	375	450	130	1950	2340
30	450	540	140	2100	2520
40	600	720	150	2250	2700
50	750	900	160	2400	2880
60	900	1080	170	2550	3060
70	1050	1260	180	2700	3240
80	1200	1440	190	2850	3420
90	1350	1620	200	3000	3600

that there can be no excuse for temporizing with hypodermoclysis or rectal instillations when there is any question of their adequacy. Twice the volume given intravenously twelve hours too late may not relieve a condition which half the volume given twelve hours "too early" would have prevented.

**Selection of Solution—1** When fluids are needed, 5 per cent dextrose in physiologic solution of sodium chloride is most often used.

**2** When excessive sweating, vomiting, diarrhea or exudation (e. g. burns) accompany the fluid loss, 5 per cent dextrose in physiologic solution of sodium chloride is used to replace salt loss.

**3** When nourishment is needed, 10 per cent dextrose in physiologic solution of sodium chloride or in water has preference.

**4** When acidosis is threatened or present, 10 per cent dextrose in salt solution or in water, or in lactate-Ringer's solution (Hartmann's solution) is used.

**5** In treating poisoning with soluble diffusible poisons (includes most of the common poisons) several liters of 5 per cent dextrose in water is used to wash the blood after the usual emergency procedures.

**6** In hypoglycemia (insulin shock) 10 per cent dextrose in physiologic solution of sodium chloride or in water is used.

**7** In diabetic coma, 10 per cent dextrose in physiologic solution of sodium chloride or in water is used. (One unit of insulin per gram of dextrose may be mixed in the intravenous flask but insulin is much more dependable when given subcutaneously. Each 10 cc of 10 per cent dextrose contains 1 Gm of dextrose.)

Dextrose 5 per cent is approximately isotonic with blood and is passed off as carbon dioxide through the lungs, placing little or no load on the kidneys. It is harmless when not needed, but usually when there is large fluid (or salt) loss there is an accompanying need for fuel, hence the almost universal inclusion of dextrose in solutions for mass intravenous injection.

Dextrose in Ringer's solution (a blood-mimicking solution containing potassium and calcium chlorides in addition to sodium chloride) is occasionally substituted

for dextrose in physiologic solution of sodium chloride wherever mentioned. This also applies to dextrose in lactate Ringer's solution (Hartmann's solution—Ringer's solution plus sodium lactate, designed to compensate for loss of bicarbonate).

**Dose**—The initial dose is usually 1,000 cc for adults. For children the dose is reduced in proportion to weight. Subsequent dosage should be sufficient to accomplish the purpose.<sup>1</sup> For fluid or salt deficiency sufficient should be given to maintain at least 1,000 cc (34 ounces) of urine daily.

After the original fluid loss has been made up, i. e., the urine is dilute (of low specific gravity), further fluid injection should equal the total fluid output. For practical purposes one may calculate the fluid output as follows:

Consider the loss through lungs, skin and normal defecation as 1,000 cc daily,<sup>2</sup> if there is increased metabolism, excessive perspiration, hemorrhage, vomiting, exudation or diarrhea, estimate these losses and add the estimated or preferably measured urinary output. Their sum is the total fluid output. Example:

Lungs, skin and defecation (considered) 1,000 cc, urine measured 1,650 cc, vomitus estimated 300 cc, total fluid output 2,950 cc. Dose for coming twenty-four hours 2,950 cc or, in round numbers, 3,000 cc.

This method of handling dosage will go a long way toward avoiding edema (including pulmonary edema), for which one should always be on guard.

For nutrition an adult weighing 140 pounds (63.5 Kg) requires at least 5,000 cc of 10 per cent dextrose solution daily if this is the only source of nourishment. (This is based on 15 calories per pound resting requirement, 18 calories with fever [33 and 40 calories per kilogram respectively]. Dextrose yields 4.10 calories per gram, 1,000 cc of 10 per cent dextrose contains 100 Gm of dextrose, which yields 410 calories.)

TABLE 3—Caloric Values of the More Commonly Used Dextrose Solutions

Volume Injected Cc	5% Dextrose Calories	10% Dextrose Calories	20% Dextrose Calories

#### EXPLANATION OF THE USE OF TABLES 2, 3 AND 4

Tables 2, 3 and 4 are designed to help in the determination of the caloric need, the selection of a suitable dextrose concentration and volume and appropriate speed of injection. Weights are expressed in pounds rather than kilograms because metric scales are not

generally available, moreover, the weight is generally estimated or taken from the patient's statement and, whether they should or should not many clinicians have difficulty in converting pounds to kilograms. At best it means another calculation. Example:

A patient without fever, estimated to weigh 140 pounds (63.5 Kg), is unable to take nourishment by other means than intravenous injection. Using table 2 or the formula of caloric requirement (15 calories per pound daily, 18 calories if the patient has fever) we find that the patient needs 2,100 calories

TABLE 4—Rate of Flow Equivalents

Cc per Minute	Cc per Hour	Cc per 24 Hours	Cc per Minute	Cc per Hour	Cc per 24 Hours
0.35	21	500	3.5	210	5 040
0.7	42	1 000	4.2	252	6 000
1.1	63	1 500	4.5	270	6 480
1.4	84	2 000	4.9	294	7 000
1.7	104	2 500	5.2	312	7 500
2.1	125	3 000	5.6	336	8 000
2.4	146	3 500	5.8	350	8 400
2.8	167	4 000	12.5	750	18 000
3.1	188	4 500	16.7	1 000	24 000
3.5	208	5 000			

daily. Table 3 shows the nearest figure to this to be 2,050 calories, which is supplied by 5,000 cc of 10 per cent solution or 2,500 cc of 20 per cent. Since 10 per cent dextrose is more nearly isotonic and yields the caloric requirement in an amount that is entirely practical to administer each day, it is the solution of choice. Table 4 shows that continuous phlebotomy at the rate of 3.5 cc per minute or 208 cc per hour will use 5,000 cc a day. If a more rapid rate of injection is desired, 8.3 cc a minute will yield 500 cc an hour. In adjusting the rate per minute it will be found that the average dextrose solution will come through the average drip meter at about 12 drops per cubic centimeter rather than 16 drops per cubic centimeter, which is the factor commonly used.

**Rate of Injection**—Dextrose solutions should not be injected more rapidly than 0.35 Gm per pound of body weight per hour, as above this rate sugar is excreted in the urine of a normal adult.<sup>3</sup> However, one could inject 10 per cent dextrose at the rate of 500 cc an hour and still be within this limit with a man of average weight.

It has been rather general practice to inject a liter of solution in from thirty minutes to an hour. Recently several have taken violent exception to this practice and have recommended up to eight hours for the injection of a liter. Those who prefer more rapid injection say that continuous phlebotomy is inconvenient and not practical, while those advocating slow injection believe that the rapid method may cause "speed shock." The man who selects a rate of flow of about 500 cc an hour for adults when there is indication neither for particularly slow nor for particularly rapid injection is treading middle ground. As a rule, hypertonic solutions (e. g. from 2 to 5 per cent saline or from 10 to 20 per cent dextrose) should be given more slowly than isotonic solutions (e. g. 5 per cent dextrose or physiologic solution of sodium chloride).

In shock, one should inject at the rate of from 20 to 40 cc per minute, constantly watching the pulse and blood pressure. When these improve to within safe limits the speed of injection should be reduced.

**Temperature of Injected Fluid**—The temperature of the solution in the flask may range between 75 and 120 F, 112 being a good average. When the patient's temperature is high, relatively cool solutions should be used. When the patient's temperature is abnormally

<sup>3</sup> Wilder, R. M. and Sansum, W. D. Glucose Tolerance. *Arch. Int. Med.* 19: 311 (Feb.) 1917.

low, solutions between 112 and 120 should be used, e g, shock. When the injections are given slowly, however, the temperature of the solution is probably of minor importance.

#### SUMMARY

Preferences for the solutions more commonly used in large volumes intravenously vary in different sections of this country. Dextrose 5 per cent in physiologic solution of sodium chloride is most often used.

Nonoriginal suggestions and the tables will aid the physician who may be confused by the confusions of current literature in determining and carrying out good common sense intravenous practice.

## DISLOCATIONS OF THE KNEE JOINT

WITH A REPORT OF A COMPLETE EXTERNAL LATERAL DISLOCATION

H EARLE CONWELL, M D

Consulting Orthopedic Surgeon Employees Hospital  
AND

R H ALLDREDGE, M D

Resident Orthopedic Service Employees Hospital  
FAIRFIELD, ALA

The knee is probably more often the site of traumatic involvement than any other joint. Complete dislocations of the knee joint are extremely rare and occur less frequently than in any of the large joints of the body. Subluxations of the knee joint, however, are very common.

The records of many large hospitals fail to show a single case of a complete dislocation of the knee. According to Ritter<sup>1</sup> in 23,000 accident cases admitted to the Reconstruction Hospital in New York, only one dislocation of the knee was noted and that one was incomplete. Ritter also states that the records of the New York Post Graduate Hospital reveal but three

Fig 1—Important ligaments of the knee joint (Cunningham D J A Text Book of Anatomy, ed 4 New York William Wood & Co 1913)

cases. One was the result of a chronic infection and the other two were forward dislocations of traumatic origin. Ransohoff<sup>2</sup> states that in 1,000 dislocations in the General Hospital at Copenhagen there were only two dislocations of the knee joint.

In a total number of about 9,000 fractures and dislocations treated by the orthopedic service of the

Employees Hospital, there were six cases of complete dislocation of the knee joint. In four of these cases the knee was dislocated anteriorly,<sup>3</sup> in one case it was dislocated posteriorly and the sixth case was an external lateral dislocation of the knee joint, which is herewith being reported in detail.

#### ANATOMY

The bony landmarks of the knee are the patella, the internal and external condyles of the femur, the condyles and the tubercle of the tibia, and the head of the fibula. The soft part landmarks are the quadriceps tendon anteriorly and the hamstring muscles and tendons posteriorly. The bones entering into the formation of the joint are the condyles and the patellar surface of the femur above, the condyles and the spinous processes of the tibia below, and the patella anteriorly.

The stability and support of the knee are dependent on its various ligaments, of which there are two sets, the external and the internal (fig 1). The external ligaments are the most important and consist of the internal and external laterals, the quadriceps and its component muscles and tendons, the patella and patellar tendon anteriorly, and the oblique popliteal and arcuate popliteal ligaments posteriorly.

In addition to these, the capsular ligament entirely surrounds the joint. The two heads of the gastrocnemius and the tendon of the semimembranosus muscle reinforce the other structures posteriorly.

The internal set of ligaments consist chiefly of the anterior and posterior crucials. The anterior crucial ligament arises from the nonarticular fossa of the tibia anterior to the tibial spine and passes upward and outward and is inserted to the posterior medial aspect of the external condyle of the femur within the intercondylar notch. The function of this ligament, as can be seen from its location, is to prevent anterior dislocation of the tibia on the femur when the knee is in extension.

The posterior crucial ligament arises from the lateral surface of the anterior portion of the internal condyle of the femur and passes to the posterior intercondylar tubercle and fossa of the tibia. This ligament prevents posterior dislocation of the tibia on the femur.

The two semilunar cartilages rest on the condyles of the tibia. They are not attached to the condyles but to the capsule by their outer margins and to the intercondylar eminence and the crucial ligaments. They are connected medially by a variable transverse ligament.<sup>4</sup>

#### ETIOLOGY, TYPES AND CLASSIFICATION OF DISLOCATION AT THE KNEE

Dislocations of the knee may be complete or incomplete and may be caused by direct or indirect violence. Incomplete dislocations are more common. They are classified according to the relation of the upper end of the tibia to the lower end of the femur. The various types are as follows:

1 *Anterior Dislocation*—This is the most common type of dislocation at the knee, about 40 per cent of all knee joint dislocations being of this type.<sup>2</sup> Anterior dislocations occur when the knee is in full extension, either when direct violence is applied to the anterior lower end of the thigh, driving the femur backward,

or when applied to the posterior upper end of the leg near the knee, driving the tibia forward. It may also occur by indirect violence, such as occurs when one is standing in a falling elevator.<sup>2</sup>

**2 Posterior Dislocations**—This type is second in frequency of occurrence, composing about 20 per cent of these dislocations.<sup>2</sup> Posterior dislocations occur while the knee is in flexion. Extreme direct violence received on the anterior upper end of the leg near the knee or on the posterior surface of the thigh near the knee usually causes this type of injury. It may also be caused by indirect violence, as occurs when one is running and steps into a hole, the leg being fixed and the weight of the whole body being thrown forward on the knee. In all posterior dislocations the posterior crucial ligament is ruptured.

**3 Lateral Dislocations**—These compose about 20 per cent of knee joint dislocations.<sup>2</sup> They are caused by forced adduction of the leg or, as happened in our case, the leg may be caught in a rotating wheel and

crucial may be torn. In posterior dislocations the posterior crucial is ruptured and the anterior may be also. The hamstring tendons, may be torn and are always unduly stretched in anterior dislocations.

In either anterior or posterior knee dislocations, all the ligaments of the knee may be torn, but usually portions of the lateral ligaments remain intact. There is usually an extensive laceration in the capsule and capsular ligament in any dislocation of the knee. A narrow tear in the capsule may necessitate an open reduction. Rupture of ligaments and tears in the capsule are usually more extensive and complete in lateral and medial dislocations. Usually all the important ligaments in these cases are ruptured, including the crucials, the laterals and the posterior ligaments. The patellar and quadriceps tendons are rarely ruptured.

Any type of dislocation may be compounded, and when this occurs it is a serious complication, especially in the anterior dislocations in which the lower end of the femur penetrates the popliteal space. Simultaneous

Fig. 2—A complete external lateral dislocation of the knee joint. Note the visibility of both condyles and the intercondylar notch of the femur. Also note the extreme degree of stretching of the hamstring muscle (B).

twisted on the thigh. It may also be caused by direct violence against the inner aspect of the leg high up or against the lower end of the thigh on the outer side.

**4 Medial Dislocations**—About 7 per cent of all cases are of this type.<sup>2</sup> The tibia is displaced medially by forced abduction of the leg or by direct violence against the external surface of the leg, high up, or against the inside of the thigh, low down.

**5 Rotary Dislocations**—This type of injury is rare. It is usually caused by the leg being caught in a rotating wheel and rotated about its long axis. There are two types, outward or inward, according to the direction of the toes.

#### PATHOLOGY

The pathologic conditions in dislocations of the knee vary according to the type of dislocation. Fractures are unusual in anterior and posterior dislocations, except for avulsion of the tibial spine. Lateral and medial dislocations are often accompanied by fractures, which may be of the internal or external condyles of the femur or tibia. The semilunar cartilages may be fractured or displaced, causing considerable difficulty in reduction. In anterior dislocations the anterior crucial ligament is always ruptured and the posterior

dislocation of the patella is extremely rare. One of our cases was accompanied by this unusual complication.

Injuries to the nerves and blood vessels in the region of the knee are not uncommon. Rupture of the popliteal artery may occur,<sup>5</sup> and gangrene may result. This is especially likely in anterior dislocations and is due to anatomic fixation of the popliteal artery.<sup>6</sup> It is possible, however, for only the intima to be injured, which may result in a delayed thrombosis and gangrene.

Aneurysms sometime develop following initial arterial injury. When a vessel is severed, the contusion and laceration of the periarticular soft parts are so great that collateral circulation is often prevented from taking place. Nerve injuries are not infrequent and may consist of a simple contusion or a complete severance of the sciatic nerve or its branches. Permanent nerve injury is rare.

#### DIAGNOSIS

The diagnosis of a complete dislocation of the knee joint is usually not difficult. In the presence of a history of extreme violence, severe pain and discomfort,

<sup>5</sup> Anderson, R. I. Dislocation of the Knee with Rupture of the Popliteal Artery and Vein. Report of a Case. *Virginia M. Monthly* 58: 120-123 (May) 1931.  
<sup>6</sup> Lipshutz, Benjamin. Injuries to Large Arteries Encountered in Civil Practice. *Surg. Gynec. & Obst.* 46: 62-71 (Jan.) 1928.

with inability to bear weight and a deformity of the knee and shortening of the extremity, one should immediately suspect a dislocation.

Roentgenograms usually prove the diagnosis. One should always look for complications. The dorsalis pedis and posterior tibial arteries should always be palpated. Evidences of nerve injury and its extent should always be looked for. A large mass in the popliteal space with an absence of pulsations in the dorsalis pedis and posterior popliteal arteries indicates a hematoma from a ruptured vessel and usually demands immediate exploration.<sup>5</sup>

Roentgenograms should be made before any treatment is instituted if the general condition of the patient permits and if there is no indication for immediate

Fig. 3—Complete external lateral dislocation of the knee joint with a chip fracture of the internal condyle of the tibia. Note the distance between the spine of the tibia and the intercondylar notch of the femur.

reduction. This will not only show the exact position of the dislocation but reveal any fractures that may be present.

#### TREATMENT

The patient's leg should be properly splinted as soon as he is seen. If shock is present this should be combated by the usual measures, certain cases, however, may demand immediate reduction if the circulation is temporarily embarrassed.

In uncomplicated cases, closed reduction should be done if possible. This is usually not difficult and can be easily accomplished by traction and pressure over the lower end of the femur with countertraction to the leg and upper end of the tibia in the opposite direction of displacement. Increasing the deformity is dangerous, as the vessels that are already on their maximum stretch may rupture. Continuous traction likewise should be avoided, as the ruptured ligaments may become permanently elongated.

Ether or gas anesthesia should be used if the patient's condition warrants a general anesthetic. Some cases

cannot be reduced by the closed method and require open reduction. A narrow tear in the joint capsule or an interposed semilunar cartilage is most often the cause of the irreducibility.<sup>8</sup> Immediate open reduction should be resorted to if closed reduction is impossible.

Compound dislocations should be reduced and the wound cleansed, debrided and sutured. A ruptured artery is a serious complication. As previously stated, when there is swelling in the popliteal space and an absence of pulsation in the dorsalis pedis and posterior tibial arteries, a ruptured popliteal artery should be suspected and exploration performed. Small openings in the artery may be sutured, but larger ones require ligation of the artery and vein whether the vein is ruptured or not. Even then gangrene may result and an amputation above the knee may be necessary.

When the dislocation is reduced, a plaster cast should be applied to extend from the base of the toes to include the hip, with the knee in slight flexion except in posterior dislocations, when the knee should be fully extended. Circulation of the foot should be closely observed. The cast should be cut immediately if circulation is impaired. In most cases prolonged immobilization should be carried out and this usually means from six to eight weeks. At the end of this time the cast is removed or bivalved and active motion and massage are carried out. The patient is then fitted with a brace (fig. 4A) which is attached to the shoe and has a detachable support about the waist with a lock joint at the knee, so constructed as to permit motion only when the patient flexes the knee. Weight bearing with crutches, physical therapy, active motion and hot baths should be continued over a long period of time.

Special attention should be given to the development of the quadriceps and hamstring muscles, especially the quadriceps. We feel that this is the most important factor in stabilizing the knee joint after extensive lacerations of the ligaments. We do not favor immediate open operation and attempt at repair of the crucial or other ligaments. We feel that this radical step is not justified in the face of results that we and many others have obtained by the closed reduction.

#### PROGNOSIS

The prognosis in dislocations of the knee is to life is good in uncomplicated cases. When complicated by rupture of the popliteal artery, gangrene occurs in from 35 to 40 per cent when ligation is done and in an even higher percentage when it is not done.<sup>5</sup> Compound dislocations of the knee are serious because of disturbance to the circulation and infection, which may result in death. Shock alone has caused death in these cases. The end functional result varies, but in uncomplicated cases, if early and proper treatment is carried out, there should result a painless, stable knee with moderate and sometimes full motion.

#### REPORT OF CASE

T. M., a white man, aged 57, 5 feet 4 inches in height (163 cm), admitted to the Employees Hospital, Nov. 1, 1934, stated that about one hour before admission he stepped into a hole about knee deep, at the bottom of which was a rotating sifting metal basket, similar to a rotating wheel. His foot was caught in the rotating basket and was twisted around, causing a severe injury to his left knee. On examination the patient was perfectly conscious with no evidence of any injury other than that of the left knee. He was not in severe shock. Examination of the left knee revealed a very striking deformity. Photographs of the dislocated knee (fig. 2) taken immediately follow

ing admission to the hospital are, so far as we know, the first ever to be published of a dislocation of this type

The width of the region of the left knee was twice that of the right. The left leg was 2 inches (5 cm) shorter than the right. The upper end of the tibia was completely lateral externally, to the articular surface of the lower end of the femur. The condyles of the femur and the intercondylar notch could easily be seen and palpated under the tightly stretched skin. Pulsations in the posterior tibial and dorsalis pedis arteries were normal, and there was no evidence of any disturbance of circulation in the foot. There was no compounding of the wound or other complications. There was every evidence of a complete external lateral dislocation of the knee joint.

Roentgenographic views were in accordance with the physical manifestations: that is a complete external lateral dislocation of the knee with an overlapping of about 2 inches and a small associated chip fracture of the internal condyle of the tibia (fig 3).

## COMMENT

According to Huber, Yaffee and Podlasky<sup>9</sup> Hey Groves advised operation and repair of the ligaments. Sir Robert Jones did not recommend any special treatment but emphasized prolonged immobilization. Meadows, quoted by Huber<sup>9</sup> cites a case in which he reduced a dislocation and applied an elastic bandage. The patient was discharged on the third day and was symptom free and walking in twenty days. This short convalescence must be unusual.

We do not believe in immediate open operation in view of the results obtained by us and many others. Weigel<sup>10</sup> reports the case of an anterior dislocation in which closed reduction was performed and the end results were excellent. Bennett, in discussing this case,

Fig 4—A type of brace used after the removal of the cast. Note that the brace is attached to the shoe and extends to the hip being supported by a leather band around the pelvis. There is a lock joint at the knee which prevents lateral motion but allows full flexion of the knee joint. B and C show the results eight months after injury at which time the brace has been entirely discarded. The left knee is stable and painless. The patient had about a 30 degree flexion of the leg at the knee joint at that time. The patient can walk up and down steps.

The patient was immediately taken to the operating room and under nitrous oxide anesthesia the dislocated knee was reduced. Traction and slight abduction of the leg were carried out by one of us while inward pressure on the outside of the upper part of the leg and countertraction was performed by the other. The leg was then held in reduction while a plaster spica cast was applied over sheet cotton extending from the hip down to the base of the toes with the knee in slight flexion.

After six weeks the cast was bivalved and massage and physical therapy were begun with active motion. In the seventh week a brace was fitted (fig 4 A) which was attached to the shoe and extended above the hip having a lock joint at the knee. The patient was then allowed to be out of bed and he began weight bearing with the aid of crutches. He was discharged from the hospital Jan 23 1935. Crutches were discarded on March 27, but he continued walking with the aid of the brace.

The brace was discontinued July 15 (fig 4 B and C) and the patient has been walking without any support since that time. He now has a stable, painless knee with about 30 degrees of flexion, with full extension of his leg at the knee joint.

stated that the crucial ligaments are not as important as they were once thought to be. Armitage Whitman, in discussing the same case, minimized the importance of the crucial ligaments and stressed the importance of developing a strong quadriceps muscle. We are heartily in accordance with Whitman's views. Whitman was also frank enough to admit that he had operated on a patient, doing a fascial transplant with poor results.

It is our opinion that dislocations of the knee should be treated conservatively, that is, by closed reduction and prolonged immobilization. We also believe that development of the muscles especially the quadriceps, is of supreme importance, since they have a great deal to do with stabilizing the knee.

10 Weigel E W Complete Dislocation of Knee. *Am J Surg* 9: 140-141 (July) 1930.

## SUMMARY

1 Complete dislocation of the knee joint is an unusual injury. Anterior and posterior dislocations are the most common types of dislocations.

2 Uncomplicated dislocations are usually simple to reduce, and the reduction should generally first be attempted by the closed method, with the knee kept immobilized for from six to eight weeks.

3 Serious complications may occur which necessitate open reduction, ligation of blood vessels or even amputation.

4 We do not favor open operation and attempt at repair of the crucial ligaments. Muscular development is highly important in stabilization after a complete dislocation of the knee.

## AN EPIDEMIC OF INFECTIOUS DIARRHEA IN THE NEW-BORN

LOUIS H BARENBERG, MD

WALTER LEVY, MD

AND

MILTON J H GRAND, MD

NEW YORK

The term infectious diarrhea is used to designate a syndrome characterized by a sudden onset of diarrhea, slight fever, dehydration, complications of the ear and respiratory tract and a high mortality. It is a distinct entity and is not to be confused with dysentery, summer diarrhea, gastrocolitis or enterocolitis. No specific organism has been isolated to account for this syndrome nor is there a characteristic pathologic picture of the gastro-intestinal tract to be noted in the necropsies. The data obtained from our study of thirty-two new-born infants who were stricken with this disease are herewith presented, first because of the tremendous havoc an epidemic of this sort may play in any nursery and secondly to acquaint the general practitioner with a condition that may be readily encountered in routine obstetric and new-born practice.

## PREVIOUS EPIDEMICS

Within the last year four such epidemics occurred in different institutions in New York City and its vicinity. A review of the literature disclosed but two references that deal to some extent with this particular condition, while the pediatric textbooks are entirely lacking in information on this subject.

In 1928 the Dicks and Williams<sup>1</sup> reported an epidemic at the Cradle, an institution which takes care of homeless infants from birth until their adoption. It is a model institution with adequate nursing facilities. This outbreak was characterized by marked dehydration, diarrhea and toxemia. In many of the infants the diarrhea was associated with otitis media and mastoiditis. Eighty-one babies contracted the disease, of whom twenty-seven died, giving a mortality of 31 per cent. Routine bacteriologic studies of the stools did not reveal any definite organism that could be held responsible for the intestinal infection. However, toward the end of the epidemic a new method of

culture was adopted and in five cases the Morgan bacillus was recovered. They concluded, therefore, that this epidemic was a primary infection of the intestinal tract caused by the Morgan bacillus. That inference may be questioned, since the study was not properly controlled. The outbreak lasted for several months and did not end until freshly boiled milk formulas were substituted for the various dried milks then used in the institution.

In 1930 Jampolis, Howell, Calvin and Leventhal<sup>2</sup> reported a study of thirty-four cases of diarrhea in the nursery of the Michael Reese Hospital. The epidemic lasted from February until the middle of June, during which time fourteen babies died, a mortality of 42 per cent. The clinical pictures of the sick infants were characterized by a marked alimentary intoxication, dehydration and high temperature. Stool cultures revealed *Bacillus mucosus* as the etiologic agent only toward the end of the second outbreak. This organism was traced to three of the attendants connected with the nursery.

In 1934 a similar epidemic broke out in a New Jersey institution.<sup>3</sup> The morbidity and mortality were very high. Bacteriologic studies did not uncover the cause of the infection. Several months later in a Queens County hospital an epidemic occurred, which persisted for several weeks. This one was identical with the others so far as the symptomatology and lack of causative organism were concerned. It required closing the nursery in order to stamp out the infection. Of the twenty-six patients that were ill, seventeen died.

In February 1935 an epidemic of infectious diarrhea appeared in the nursery of a Brooklyn hospital. During the first month only a few babies contracted the disease and the infection apparently subsided. The following month the number of cases assumed epidemic proportions, spreading from the ward nursery to the private nursery on the floor above. This series of cases was characterized by a low-grade fever, loose stools and signs of upper respiratory infection. Several babies had otitis media, while others had bronchopneumonia. Vomiting was a prominent feature and intestinal intoxication was apparent. Continuous intravenous medication was to no avail. Of the thirty-three infants who contracted diarrhea twenty-three died. The epidemic was not checked until the nurseries were closed. Intensive bacteriologic studies of the stools and nasopharyngeal secretions were carried out in the hospital laboratories and rechecked by the New York City Health Department Laboratories, but no etiologic organism was found.

During this time a similar epidemic was raging in the nursery of a Manhattan hospital. Here too the morbidity and mortality were high and again thorough study failed to expose an organism. At the time of this writing three more epidemics are raging in large hospital nurseries in New York City.

## CLINICAL REPORT

It is quite evident that infectious diarrhea in the new-born is a definite clinical entity and may occur in epidemic form in well regulated hospital nurseries, also that, despite the intensive investigations, the mode of transmission and the causative agent have not been determined.

Read before the Bronx Pediatric Society, Oct. 9, 1935.  
From the Pediatric Department of Morrisania City Hospital.  
1. Dick, G. F., Dick, Gladys H. and Williams, J. L. The Etiology of Enteritis Associated with Mastoiditis in Infants. *Am J Dis Child* 35: 9-5 (June) 1928.

2. Jampolis, M., Howell, Katharine M., Calvin, J. K. and Leventhal, M. L. *Bacillus Mucosus* Infection of the New Born. *Am J Dis Child* 43: 70 (Jan) 1930.

3. The names of the institutions are omitted since no report of the epidemic has been publicized.

The outbreak of infectious diarrhea in the nursery of Morisania Hospital began July 10, 1935. The census at the time was forty-three infants. Of these, thirty-two infants, which included four premature infants, contracted the disease. Fourteen babies died July 20 the epidemic terminated abruptly. The morbidity, then, was 74 per cent and the mortality 43 per cent.

All the infants who were subsequently stricken had been thriving normally, when the first manifestation of illness was a slight anorexia. Ordinarily the refusal of a feeding by a new-born infant is not considered an alarming symptom and is very often overlooked in a nursery. However, when it is associated with a low-grade fever, investigation is always imperative. The temperature was not, as a rule, high during the course of the epidemic. This was so in both the mild and the severe types of cases. In eighteen infants the temperature range was from 98.2 to 101 F, in the others it ranged from 101 to 103, as shown in the accompanying table.

Diarrhea appeared almost from the very onset of the disease. The average number of stools per day was six, the largest number in any case being twelve. The stools were yellow or greenish, watery, and explosive in character with many bubbles, resembling fermentative stools. Slight mucus and curds were present, but no blood. The reaction of the stools was markedly acid to litmus paper. This apparent fermentation of the stools was not due to excessive amounts of sugar, as the supplementary feedings were made of simlac, to which sugar is not added. The marked acidity of the stools may probably have been due to fatty acids resulting from an interference with proper fat absorption in the intestinal tract. It was interesting to note that the reaction of the stools ran parallel with the general condition of the infant. We soon learned from clinical observation that when the reaction became alkaline the number of stools diminished and they were of a better consistency. The change in reaction in

Chart 1—Weight curves from onset of diarrhea in infants who recovered

most cases occurred at the end of forty-eight hours. In no instance did the stool become alkaline in the fatal cases. In one case an infant who began to improve, having alkaline reaction of the stools, suddenly showed a reversal of the reaction and a relapse of the diarrhea occurred.

Vomiting was not a special feature of this syndrome. Only a few infants vomited excessively. The average loss of weight in the infants who recovered was

8 ounces (225 Gm). It is to be noted that the loss of weight, which was only gradual, occurred mainly in the heavier babies. The loss in the small infants was insignificant, which is the usual experience under normal circumstances (chart 1). Dehydration was only moderate in the uncomplicated cases. In the fatal ones (chart 2), however, water loss was rather marked and rapid. The average loss of weight was 23 ounces (650 Gm). Even babies under 5 pounds (2,268 Gm) lost considerably. Intoxication, on the other hand, did

Chart 2—Weight curves from onset of diarrhea in infants who died

not play an important role in this epidemic, only one infant was moderately toxic. In other words, this syndrome did not present the characteristic picture of alimentary intoxication.

The age at the onset of the diarrhea varied from 2 to 20 days (chart 3). The fact that seventeen infants developed diarrhea on the sixth day after birth indicated a short incubation period for this infection. The duration of the illness was from six to twenty-six days, the average time for recovery being ten days.

The complications were mainly those related to the respiratory tract. Seventeen infants showed evidence of either catarrhal or purulent otitis media. The ear infection occurred in most instances at the beginning of the disease. In the others it developed soon after the diarrhea was established. In no case was the ear infection a terminal manifestation. Myringotomy was performed in all cases of otitis media. In a few infants free drainage was established. Anthrotomy was advised in one instance in which the aural drainage was profuse, but the infant died of bronchopneumonia before the operation was performed. Thirteen infants developed clinical evidence of pneumonia. Eleven of these infants contracted this complication in the early stages of the disease. In the others it was a terminal pneumonia.

To illustrate the type of cases we were dealing with, we are presenting two case reports. One represents the milder and uncomplicated type, while the other typifies the severe case complicated by pneumonia or otitis media.

**CASE 1 (recovered)**—K, a boy, was 15 days of age at the onset of diarrhea. He was a full term infant delivered by forceps. Nothing abnormal was noted in his physical exam-

ination except a subperiosteal hematoma. Roentgenographic examination of the skull failed to reveal any abnormality of the bones. Circumcision was performed on the eighth day without any ill effects. After an initial loss of 8 ounces (227 Gm) during the first four days, he regained his birth weight by the tenth day, 7 pounds 3 ounces (3,260 Gm). July 10, at the age of 14 days, slight anorexia was noted. The next day he had an elevation of temperature to 101 F, associated with loose, greenish yellow, acid stools. Up to this time he had been receiving breast milk and simlac. These were replaced by a half ounce (15 cc) of protein milk, with 3 per cent carbohydrate, alternating with one-fourth ounce (8 cc) of 1 per cent saline solution, given at hourly intervals. He was transferred to the pediatric ward and kept on this routine feeding under aseptic technique. After three days the stools became alkaline and he began to gain weight. The protein milk was gradually increased to 3 ounces (90 cc) with an addition of 5 per cent carbohydrate, and saline solution was discontinued. Finally, evaporated milk was used exclusively. He was discharged as cured July 20, nine days after the onset of illness, weighing 7 pounds 13 ounces (3,544 Gm).

CASE 2 (died).—R, a boy, was a normal full term baby, weighing 7 pounds 14 ounces (3,572 Gm) at birth. After an initial loss of 12 ounces (340 Gm) he gained weight for two days and then remained stationary at 7 pounds 6 ounces (3,345 Gm) until the onset of diarrhea at the age of 15 days. On this day he lost 12 ounces (340 Gm) and had an elevation of temperature to 102.6 F. He had seven loose, watery, greenish, acid stools. The temperature was 100 the following day and afterward varied from 100 to 98.6. A bilateral

Chart 3—Age at onset of diarrhea

myringotomy was performed two days after the onset of illness. No exudate was noted at first, but two days afterward a mucoid discharge was seen in the left ear. The patient did not respond to the routine treatment and began to vomit. A starvation period was instituted, a stomach lavage was done and fluids were given by hypodermoclysis. Following this procedure the baby retained alternately small quantities of protein milk and saline solution. On the third day of illness signs of bronchopneumonia were elicited over the left lower lobe. His general condition was critical. Oxygen therapy was instituted. The pneumonia subsequently migrated to the right upper lobe. Extreme cyanosis, pallor and marked respiratory embarrassment, with terminal pulmonary edema then followed. There was a loss in weight of 26 ounces (737 Gm). A postmortem examination revealed bilateral bronchopneumonia, parenchymatous degeneration of the liver, heart and kidneys and an acute splenitis while the gastro-intestinal tract showed no characteristic changes.

#### PROGRESS OF THE EPIDEMIC AND METHOD ADOPTED FOR ITS CONTROL

July 10 we were informed that two of the premature infants were having frequent diarrheal stools. Examination revealed that one showed some evidence of an infection of the upper respiratory tract with involvement of the right ear. The infants were isolated and isolation precautions ordered. The next day two more infants developed diarrhea. The gravity of the situation was then realized and it became evident that we were dealing with an impending epidemic. In view of the fact that these infants, in addition to the gastro-intestinal disorder, also presented evidence of infection of the upper respiratory tract, the consensus was that

we were not confronted with a primary intestinal infection but with a symptom complex parenteral in origin.

In the hope of checking the spread of this infection the following procedure was instituted. All the infants affected were immediately transferred to the pediatric ward from the nursery. A special nursing staff was assigned to these children. Face masks were worn by this entire staff. The nurses were required to put on a fresh pair of sterile rubber gloves for each feeding of each infant, for it is conceivable that the hands which may have become contaminated in changing the diapers of an infected baby might, in spite of washing, contaminate another in the process of applying the nipple to a bottle. Evaporated milk mixtures were substituted for simlac.

Despite these precautions, three more infants came down with diarrhea in the next two days. Evidently all the infants in the nursery had already been exposed and consequently could not have been benefited by the measures instituted. Therefore, all the recently newborn infants were placed in a separate isolated room and were taken care of by special nurses, who did not come in contact with the nursery infants.

As we watched the rapid spread of the epidemic from day to day we were impressed with the idea that we were dealing with a condition similar to an airborne disease of apparently short incubation period. This belief was further strengthened by what occurred the following day. In addition to the new cases of diarrhea in the nursery, an infant who had been kept alone in a distant isolation room for some time on account of gonorrheal ophthalmia and had been cared for by a special nurse, developed diarrhea and a clinical picture similar to those cases in the nursery. All our efforts to curb the epidemic had apparently failed. The nursery, therefore, was closed on the fifth day of the siege and the search for an etiologic factor, which was begun on the third day, became an intensive study.

In their bacteriologic studies of dried milk employed in infant feedings, the Dicks<sup>4</sup> had found that cultures from the preparations contained a variety of living bacteria. Most of the infants in our nursery had been receiving simlac as a supplementary food when the outbreak occurred. Our attention was therefore directed to this powdered milk as the source of the intestinal disorder. A check-up of the diet revealed that the type of feeding was apparently of no etiologic significance. The infants were affected whether they had been previously fed breast milk exclusively, mixed feedings with simlac, or simlac alone. It may be of interest to note that culture studies from several specimens of the simlac revealed no pathogenic organisms.

The possibility of a carrier among the persons in contact with the infants was considered. Nasopharyngeal cultures from doctors, nurses, ward maids and the infants themselves were studied. These cultures were negative for the Friedlander bacillus, *Bacillus coli*, staphylococcus and streptococcus. Cultures were made from the stomach washings of two infants who had persistent vomiting. In both of these examinations *B. coli* was found. This unusual finding would suggest that this syndrome might be associated with a decrease in gastric acidity and thereby favored the growth of the colon organism. It was deemed unwise to make gastric analyses in these infants because their

<sup>4</sup> Dick, G. F. and Dick, Gladys H. The Bacteriology of Dried Powdered Milk Preparations Employed in Infant Feeding. *Am. J. Dis. Child.* 34: 1040 (Dec) 1927.

general conditions did not warrant it. The blood cultures taken from several babies who were gravely ill gave uniformly negative results. *B. coli* was found in cultures taken from the umbilical cords. This is not an unusual finding. Cultures from the rubber nipples, as well as from the nipples of the mothers' breasts whose infants developed diarrhea, were negative. Cultures taken following paracentesis of the eardrums in all cases of otitis media revealed *B. coli* in three instances and *Staphylococcus albus* in three others.

In order to determine whether this disease was a primary infection of the intestinal tract, repeated stool cultures were taken from all the infants. These were examined for organisms commonly associated with primary intestinal disorders such as typhoid, paratyphoid and *B. enteritidis* infection. With the exception of a positive culture in one infant, all were negative.

## TREATMENT

Treatment had little effect on those babies whose illness was complicated by pneumonia. The disease took a high toll of infant life irrespective of the type of treatment employed. This has been the experience in the other institutions as well. For instance, in the Brooklyn epidemic, in which continuous venoclysis and transfusion were employed, the mortality was higher than ours, in which intravenous therapy was not used.

In vomiting infants the treatment was begun with the cessation of all attempts at feeding for twenty-four hours. Stomach lavage was done only when the excessive vomiting could not be controlled. The necessary amount of fluid to prevent dehydration was given subcutaneously. After the vomiting stopped the infants were treated according to the plans outlined later.

## Summary of Observations

Case No.	Birth Weight Lbs Ozs		Lowest Weight Lbs Ozs		Weight Loss Ozs	Dehydration	Intoxication	Days to Regain Weight from Onset of Illness	Age at Onset Days	Duration of Illness Days	Temperature Onset F	High Temperature F	Outcome

A O R = child released at own risk

The culture of the stool of this infant contained an organism which apparently belonged to the paratyphoid group but agglutinated for typhoid. The exact organism in this case has never been satisfactorily identified.

Stool cultures from the nurses and interns assigned to the nursery disclosed normal results. The stool of one nurse was positive for the bacillus of paratyphoid, Flexner type, on one occasion. The agglutination test in this case was also positive for the organism. Subsequent examinations of this nurse's stool failed to show the presence of the organism again.

Cultures were made from various levels of the intestinal tract at necropsy. These revealed only *B. coli*. *Staphylococcus albus* was found in the lung abscesses in two cases. Cultures from the various organs yielded no abnormal observations.

All these bacteriologic studies were corroborated by the laboratories of the New York City Health Department.

No starvation period was considered advisable in infants who suffered from diarrhea alone. It should be emphasized that continuous and protracted starvation leads to serious nutritional disturbances. We were aware of the fact, however, that these patients did better on small amounts of food given at frequent intervals, no attempt being made, for the first few days, to satisfy the full caloric requirement of the infant. The prevention and correction of the dehydration were considered of prime importance. We felt that the marked acidity of the stools indicated the employment of a food that would facilitate fat absorption and change the intestinal flora. Accordingly, the infants were given one-half ounce (15 cc) of protein milk with 3 per cent carbohydrate alternating with 1 ounce (30 cc) or more of 1 per cent salt solution every two hours. In this manner adequate amounts of fluid and salts were administered. It was not found necessary, in most cases, to resort to the hypodermoclysis. The protein milk and saline solution were well

taken and retained. Not only was the loss of weight being controlled, but in many instances there was an increase in weight within forty-eight hours. In order to investigate the presence of occult edema, the McClure-Aldrich<sup>5</sup> test was done in several selected babies. This test consists of an intracutaneous injection of 0.2 cc of an 0.8 per cent solution of sodium chloride. The time required for the absorption of the bleb is usually fifty minutes in normal infants. If occult edema exists, the absorption is more rapid. Our cases showed no abnormal results. As the number of stools decreased, the amount of salt solution was diminished and a corresponding amount of protein milk was added to the diet.

In addition to the foregoing treatment, 5 minims (0.3 cc) of epinephrine 1:1,000 was administered by hypodermic injection every three hours during the acute stage of the disease. This was done to prevent circulatory collapse with rapid pulse and falling blood pressure. A few days before the infants were discharged, their diet was changed to evaporated milk mixtures. Early paracentesis was done in all babies who presented pathologic appearances of the abdomens. Our impression was that this procedure did not alter the course of the disease.

#### NECROPSY RECORDS

Of the thirteen infants that died in the hospital, autopsies were obtained in twelve (92 per cent). The one infant for whom no postmortem examination was permitted had a bilateral purulent otitis media and died with signs of an extensive bronchopneumonia.

#### GROSS EXAMINATION

The lungs in most cases (ten) showed pneumonic consolidations, lobular in character, with areas of atelectasis and edema. In two instances, in addition to the pneumonia, the lungs also presented abscesses. In one of these there was an additional right-sided pleural effusion.

The spleens showed a constant picture in all the cases, namely, marked congestion and a diminution of the lymphoid tissues. Three cases presented areas of hemorrhage.

The gastro-intestinal tract showed a normal mucous membrane, no enlargement of Peyer's patches or mucoid follicles, no ulceration or lesions suggestive of dysentery or typhoid. The sole abnormal finding in five cases was the presence of hyperemic spots in the mucosa of the intestine, which was suggestive of enteritis. The other organs showed the characteristic changes of general toxemia. Parenchymatous degeneration was particularly noted in the livers, kidneys and hearts. No hemorrhages were found in the adrenals.

#### MICROSCOPIC EXAMINATIONS

The outstanding features of the microscopic pathologic examinations were as follows. The lungs on section showed partially collapsed air vesicles in some instances and exudation and edema in others. There was also an accumulation of cells, most of which were of the mononuclear or fibrocytic type. An occasional lymphocyte and polymorphonuclear leukocyte were seen. Neither the typical fibrin accumulation of the early stage of lobar pneumonia nor the marked polymorphonuclear reaction in the alveoli of late lobar pneumonia was observed.

The spleens showed marked congestion with hemorrhage, decrease in lymphatic tissue and an increase of the large mononuclear cells. These changes were noted in eleven cases.

The livers showed fatty infiltration in three cases and cloudy swelling in six. The kidneys showed cloudy swelling in seven cases and congestion in two. There was no definite lesion noted in the gastro-intestinal tract except a questionable erosion of the surface mucosa in two cases. One adrenal showed microscopic hemorrhage and congestion. The remaining organs presented nothing unusual.

#### CONCLUSION

Infectious diarrhea is a definite clinical entity that may occur during the neonatal period. Early recognition of the seriousness of this intestinal disorder is imperative. Since reduction of the morbidity and mortality depends largely on the immediate measures taken to prevent the spread of an epidemic, early treatment of this disorder is necessary before the condition becomes grave as a result of dehydration and its associated toxicosis.

It is apparent that we were confronted with a specific syndrome limited to the neonatal period. This contention is based on the fact that no infant or older child exposed to the infection in the general pediatric ward succumbed to this disease.

In spite of careful clinical observations, intensive bacteriologic studies and postmortem examinations, we were unable to uncover the causative agent or the mode of its transmission to the newborn. The occurrence of these various epidemics without disclosing a uniform etiologic organism suggests the possibility of this syndrome being the result of a virus infection.

An interstitial type of pneumonia caused by a specific virus has been demonstrated experimentally in the lungs of a monkey.<sup>6</sup> As an atypical pneumonia was constantly present in our cases, Rivers, who has been investigating this question, suggested that a specific virus might be the causative agent in our epidemic. He believes that certain toxins of the colon bacillus may produce a clinical picture such as we have observed and an atypical pneumonia as observed in our necropsies.

#### SUMMARY

1 An epidemic of infectious diarrhea parenteral in origin, occurred, thirty-two infants presenting a characteristic syndrome.

2 There was no relationship between the normal type of feeding and the incidence of the disease.

3 Dehydration was evident, but true alimentary intoxication was noted in only one instance.

4 Otitis media and bronchopneumonia as complications were frequent.

5 The severity of the disease decreased with the return of alkaline stools.

6 Bacteriologic studies failed to reveal a causative organism.

7 The administration of 1 per cent salt solution orally was well tolerated and obviated the use of the intravenous route for nutrition or medication.

8 Necropsies did not show a pathogenic picture in the gastro-intestinal tract to indicate a primary intestinal infection.

9 The finding of pneumonia with mononuclear infiltration in the absence of any intestinal lesions suggested the possibility of a virus infection.

THE EFFECT OF IODINE IN  
ADENOMATOUS GOITER

WITH ESPECIAL REFERENCE TO TOXIC ADENOMAS

ARNOLD S JACKSON, MD

AND

H E FREEMAN, MD

MADISON, WIS

There is some misunderstanding even yet, among certain of the profession with regard to the action of iodine in the various types of goiter.

It is generally recognized that iodine in any form (we use aqueous solution of iodine Lugol's solution, as a routine) causes a very beneficial response when used in exophthalmic goiter. This occurs practically without exception, but the iodine is especially useful in the preoperative treatment of exophthalmic goiter.

We do find "iodine fast" cases of exophthalmic goiter or patients who have been overtreated with iodine. These patients, as a result either of a developed tolerance to iodine or of excessive overactivity of the thyroid, finally reach a stage at which their toxic symptoms fail to recede with iodine medication and may even progress. We do not know just how or why this occurs, but it does occur. To be entirely on the safe side, one should not persist too long in iodine medication even in exophthalmic goiter.

Our object in this paper, however, is to present again to the profession the effect of iodine in adenomatous goiter. It has been known for over a century that iodine administered in adenomatous goiter often resulted in injurious effects. Marine<sup>1</sup> notes that Coindet made this observation in 1821.

These "injurious effects," of course are the development of symptoms of thyrotoxicosis brought on by the iodine. We have observed many of these cases and table 1 presents a partial list of such patients who have been operated on. The period of ingestion of iodine and the time of onset of symptoms are closely correlated, even though many of these patients have had nontoxic adenomas for years.

In a previous paper presented before the American Society for the Study of Goiter in 1924, one of us<sup>2</sup> presented a series of eighteen cases of adenomas of the thyroid made toxic by the use of iodine. The term iodine hyperthyroidism was suggested for this condition, which was presented as a distinct clinical entity. It was recognized that this syndrome had long been observed, Kocher<sup>3</sup> having described it as iod-Basedow's disease. Since this condition occurs only in the presence of an adenomatous goiter and since it does not result from the use of iodine in a normal thyroid gland, the term iodine hyperthyroidism in an adenomatous goiter was suggested as best describing this entity. So great was the reputation of Kocher and so strong was the impression made on the medical profession of the associated danger of iodine and exophthalmic goiter that in spite of several reports in the literature to the contrary the use of iodine in exophthalmic goiter was thought to be attended with great danger until Plummer pointed out this misconception in 1922.

Means and Lerman,<sup>4</sup> among others, have felt that hyperthyroidism was not induced in adenomatous goiter by the use of iodine. They say "we are very doubtful, however, of the existence of iod-Basedow, having never ourselves seen any convincing evidence of it."

Either the people of Boston must be educated to the point of refusing to take iodine in the presence of an adenomatous goiter or conditions there must differ from those in Switzerland, Ohio, Wisconsin and many other sections of this country as well as many other countries in which cases of iodine hyperthyroidism (iod-Basedow) in adenomatous goiter have been frequently observed.

Marine<sup>1</sup> states

There is sufficient evidence to show that there is a real danger in giving iodine to individuals with adenomatous goiter, and unquestionably the more concentrated iodized salts (from 1 10,000 to 1 5,000) cause injurious effects (iodine-Basedow's disease) in this particular group of patients while such doses as is well known have no injurious effects in normal individuals or in individuals with simple parenchymatous goiter. The elimination of this group with long standing adenomatous goiter I believe will largely prevent the occurrence of iodine-Basedow's disease and remove the most important objection to generalized iodine prophylaxis.

Marine further calls attention to the reports of Plummer and of McClure, which showed a distinct increase in the number of goiter operations in the years 1926 and 1927 in Michigan and Minnesota. This increase occurred mainly in the group of patients with long standing adenomatous goiters (so-called toxic adenomas) who had undoubtedly received too much iodine.

This authoritative conclusion of Marine tends to confirm the contention<sup>5</sup> of the danger of induced hyperthyroidism in adenomatous goiter from the injudicious use of iodine, as pointed out by a series of eighteen such cases in 1924. At that time this contention was refuted by Plummer and others but the literature of the past decade has contained numerous references indicating the danger of iodine in adenomatous goiter.

Thus Collier<sup>6</sup> states "Iodine after 30 in individuals with adenomatous goiter does not cure and may precipitate hyperthyroidism."

Schwytzer<sup>7</sup> feels that iod-Basedow, as Kocher termed it, is a toxic condition. Such a patient looks emaciated, has tremor combined with nervousness, and is excited and anxious.

Clute and Mason<sup>8</sup> in an article from the Lahey Clinic reported having seen nontoxic adenomas become toxic after long continued iodine feedings.

McCarrison<sup>9</sup> opposes the indiscriminate use of iodine as a prophylactic measure as both unscientific and dangerous.

Dinsmore<sup>10</sup> has seen many cases of iodine hyperthyroidism.

Boothby<sup>11</sup> notes that unfortunately even now Kocher's warning against the danger of the administra-

tion of iodine in adenomatous goiter is often not heeded and, as a result, many patients are rendered hyperthyroid

As previously stated, Means and Lerman<sup>4</sup> express doubt that iodine will produce thyrotoxicosis. Reports of such cases in large number by various competent investigators, however, as well as our own studies and the accompanying tables, present satisfactory evidence to the contrary.

We hold to the opinion that iodine, injudiciously administered, may be and often is the precipitating factor in producing thyrotoxicosis from a previously nontoxic thyroid adenoma.

De Quervain<sup>12</sup> holds a similar view. He believes that whereas incredible quantities of iodine can be borne without any thyrotoxic disturbance by most individuals who have normal thyroid glands, with goiter sufferers it frequently happens that daily doses of from

The study shown in table 1 is in line with this. Even though we present one case in which a woman, aged 29, had had an adenoma for fifteen years, it will be noted that she had been taking iodine for two years before the toxic symptoms became apparent to her. Thus a simple adenoma, even in a young individual, is a definite contraindication for iodine.

Especially do we want to call attention to the effect of aqueous solution of iodine in toxic adenomas. Although the literature since the publication of Plummer's epoch making article on the use of aqueous solution of iodine in exophthalmic goiter in 1923 has been voluminous, but scant mention has been made of the effect of iodine in toxic adenomas. In effect the action of iodine has been said to be variable and much less impressive.

Younans and Kampmeier<sup>14</sup> of the University of Michigan, however, reported that the effect was essen-

TABLE 1—Iodine Hyperthyroidism

Sex	Age	Onset of Symptoms	Weight Lbs. Pounds	Basal Metabolic Rate	Heart	Blood Pressure	Pulse	Iodine	Comment

♀	34	4 years	8	+40%	Tachycardia	150/88	120	4 years ago began taking iodine for 2 years	Tremor

0.5 to 1 mg. of iodine causes iod-Basedow to develop which lasts for months if not even for years.

We believe that this note of warning has not been without effect, and whereas it was a rather common practice ten years ago to use iodine freely for all types of goiter, the profession now has become more discriminating in the dispensing of this drug. As a result, cases of iodine hyperthyroidism are now becoming as unusual as are the crises in exophthalmic goiter. When the profession generally is cognizant of the danger of the prolonged use of iodine in exophthalmic goiter as suggested in a report of fifty-seven cases including four deaths in 1930, we<sup>13</sup> feel that there will be a general lowering of the death rate in exophthalmic goiter throughout the country, just as there has been in iodine hyperthyroidism.

It has been shown that adenomatous goiter does not become toxic in patients less than 30 years of age unless this is brought on by the injudicious use of iodine.<sup>5</sup>

tially the same as that seen in exophthalmic goiter. Therefore, they concluded that no essential difference in the pathogenesis of toxic adenoma and exophthalmic goiter can be assumed to exist on the basis of their response to treatment with iodine.

Since the response to iodine in exophthalmic goiter and toxic adenoma is so essentially different, it is difficult to conceive the idea of those who maintain that these two clinical entities are but variations of the same disease.

Means and Lerman<sup>4</sup> also state that patients with toxic adenoma respond to iodine as do those with typical exophthalmic goiter and that this response is constant and specific and will occur at any stage of the disease.

We cannot concur with this belief at all. Our toxic adenoma cases show many instances in which not only was the basal metabolic rate increased after aqueous solution of iodine, but the various symptoms of hyperthyroidism were aggravated noticeably.

We do notice improvement in toxic symptoms, including the basal metabolic rate, in many of our cases.

12 De Quervain F. The Pathological Physiology of Endemic Thyropathy. In Report of the International Conference on Goiter Aug. 24 to 26, 1927. Bern. Hans Huber. 1929. p. 124.

14 Youmans J. B. and Kampmeier R. H. Effect of Iodine in Toxic Adenoma. *Arch. Int. Med.* 41: 66-74 (Jan.) 1928.

following aqueous solution of iodine but it is impossible to estimate just how much of this is due to rest, quiet, sedation and symptomatic treatment and how much is due to the iodine

In a certain percentage of toxic adenomas, however, iodine definitely has a detrimental effect

One of us (H E F) has recently reviewed a series of 279 typical toxic adenoma cases in which operation was done at the Jackson Clinic between 1925 and 1935

The basal metabolic rate is the most tangible factor available for estimating the degree of thyrotoxicosis, and we were able to make some interesting observations in this respect

Our study shows that when we consider all the cases we might conclude that aqueous solution of iodine does have a beneficial effect because the average basal metabolic rate in the whole series was found to be decreased following iodine

None of the patients in this study had a basal metabolic rate higher than +64 per cent before the administration of aqueous solution of iodine, and the average basal metabolic rate was +34.1 per cent After the

Not only do our studies and those of Goetsch differ from those of Means and Lerman, but they are in marked contrast to those of Youmans and Kampmeier made at the University of Michigan They reported that the response to treatment with iodine in thirty unselected patients with toxic adenoma who were previously untreated with iodine was essentially the same as that seen in unselected cases of exophthalmic goiter In a later report from the surgical department of Michigan, however, Potter and Morris<sup>16</sup> reported that 36 per cent of the cases of toxic adenomas showed retractoriness to iodine or an accentuation of the symptoms (so-called iodine induced hyperthyroidism)

#### SUMMARY

1 There may be produced iodine fast cases of exophthalmic goiter

2 Iodine not only does no good but is definitely contraindicated in nontoxic adenomas of the thyroid

3 There is danger in administering iodine in cases of adenomatous goiter, of producing "iodine hyperthyroidism"

TABLE 2—Cases of Toxic Adenomas Made Worse by Iodine

Sex	Age	Basal Metabolic Rate		Heart	Blood Pressure	Pulse	Comment
		Before Aqueous Solution of Iodine	After Aqueous Solution of Iodine				
♀	38	+15%	+24%	Tachycardia dyspnea	100/80	110	Tremor nervousness
♀	41	+40%	+42%	Dyspnea	160/90	120	Tremor nervousness weakness adenoma for 30 years
♀	57	+22%	+30%	Palpitation	150/88	110	Weak lost 20 pounds in 4 years died 1 year after operation with toxic heart disease
♂	62	+42%	+58%	Tachycardia dyspnea	100/88	100	Weak lost 40 pounds in 1 year
♀	61	+86%	+33%	Palpitation auricular fibrillation	164/98	110 (irregular)	Lost 7 pounds in 2 months weak
♀	27	+33%	+31%	Dyspnea tachycardia	140/80	110	Weak nervous adenoma for 15 years
♀	60	+22%	+34%	Dyspnea auricular fibrillation	168/96	114 (fibrillating)	Goiter 30 years weak nervous
♀	50	+33%	+33%	Auricular fibrillation	180/80	97	Had had three nervous breakdowns
♀	60	+17%	+23%	Fast extrasystoles	110/100	132	Tremor
♀	62	+39%	+43%	Auricular fibrillation dyspnea	140/110	126	Tremor

administration of aqueous solution of iodine no rate was higher than +56 per cent, and the general average had been decreased to +26.9 per cent

Further study, however, reveals that approximately 62 per cent were benefited or were not affected and in approximately 38 per cent of the cases the basal metabolic rate, tremor tachycardia and the like were definitely made worse by iodine

Of those cases aggravated by aqueous solution of iodine, the basal metabolic rate increase varied from 1 to 13 points and averaged +5.8 per cent If these patients had been continued on iodine, the basal metabolic rate would undoubtedly have become elevated still further and the symptoms of hyperthyroidism aggravated still further

Table 2 presents from our study typical cases in which the basal metabolic rate and the toxic symptoms were definitely increased by the administration of aqueous solution of iodine

Attention is directed primarily to the basal metabolic rate for purposes of comparison of the conditions before and after the ingestion of iodine

Our observations on the effect of aqueous solution of iodine in toxic adenomas are similar to those of Goetsch<sup>15</sup> who reported that in a series of thirty-eight cases 45 per cent either showed no change or were made worse

4 Adenomatous goiter does not become toxic before the patient has reached the age of 30 unless the toxicity is brought on by the injudicious use of iodine

5 We have shown that iodine may and does produce thyrotoxicosis in adenomatous goiter as opposed to the contention of Means and Lerman

6 The effect of aqueous solution of iodine in toxic adenoma is not constant or specific and is not the same as that produced in exophthalmic goiter

7 Approximately 62 per cent of all cases of toxic adenoma are benefited by iodine or are not affected, while 38 per cent are made worse

8 In a series of cases of toxic adenomas, toxic symptoms and the basal metabolic rate were aggravated by aqueous solution of iodine

9 Owing to its variability of action, we believe that iodine should be given as a routine in all cases of toxic adenoma before and after operation, because two thirds of the cases will be improved and the harmful effect on the other third is negligible over a short time

#### CONCLUSIONS

1 Iodine should not be given to patients with nontoxic thyroid adenomas

2 The condition termed iodine hyperthyroidism is a definite clinical entity

3 Aqueous solution of iodine has an inconstant effect in toxic adenomas

## POPLITEAL ANEURYSM

WITH REPORT OF A CASE

ARTHUR H. WELLS, M.D.

DULUTH, MINN.

CLAY E. COBURN, M.D.

AND

M. A. WALKER, M.D.

KANSAS CITY, KAN.

It is not generally known that, with the exception of aneurysms of the aorta, popliteal aneurysms are found more frequently than those of any other artery.<sup>1</sup> According to Matas,<sup>2</sup> they are by far the most frequent of the surgical and operable types of the disease. Because of this frequency, their characteristic rapid progression and the efficacy of proper surgical intervention, a brief review of the subject will precede the presentation of a case illustrating tragic characteristics of the disease.

The agencies that weaken or traumatize the walls of other arteries, causing their dilatation, may cause the same variety of aneurysms of the popliteal artery. Trauma is a comparatively frequent factor and usually results in arteriovenous aneurysms and false aneurysms the walls of which are not made of any tunic of the artery wall but are composed of blood clot and surrounding fibrous structures.<sup>3</sup> A false pocket or fistula may thus be formed. Arteriovenous communications are designated "aneurysmal varix" or "varicose aneurysm," according to whether the fistula is direct or has an interposed false aneurysmal sac.

Arteriosclerosis is frequently the only demonstrable disease of the dilated walls. Trauma or strain may precipitate the dilatation or the symptoms of these cases.<sup>4</sup> A spontaneous or traumatic tear through an atheromatous vessel wall is another source of false aneurysm.<sup>5</sup>

The statistics of Stokes,<sup>6</sup> Garland<sup>7</sup> and Lucke and Rea<sup>8</sup> reveal syphilitic aneurysms as being far more common in larger arteries. However, in spite of an appalling lack of histologic proof, the frequency of 4 plus Wassermann tests associated with popliteal aneurysms leaves little doubt as to the importance of this etiologic agent.<sup>9</sup> Septic emboli bearing a variety of bacteria theoretically may grow on the intima or in the vasa vasorum of any blood vessel and through erosion lead to a mycotic (infectious) aneurysm.<sup>10</sup> It is doubtful whether congenital aneurysms of this moderately large artery ever occur, and no report has

been found of a dissecting aneurysm separating its relatively thin coats.

Because of its size and peculiar location it is thought that compression of the popliteal artery with the knees flexed and simultaneous exertion may put an unusually severe strain on its walls, causing small tears in the elastic fibers of the media in diseased vessels. There may be no immediate effect or, according to Delbit (cited by Matas<sup>11</sup>) it may be severe enough to cause prompt thrombosis of the artery. Repeated small tears may lead to its gradual weakening and dilatation.

As a whole, popliteal aneurysms vary from others in that they generally progress more rapidly and are subject to frequently unheralded, sudden complications. A laminated clot often partially fills the dilated lumen and rarely shows any evidence of fibroblastic organization. This clot may break loose and occlude the lumen, causing a dry gangrene. According to Matas,<sup>11</sup> spontaneous gangrene occurs more frequently with thrombosis of the popliteal variety than with any other aneurysm. Moist gangrene may result from mechanical interference with the venous as well as with the arterial circulation. Should the collateral circulation be sufficient, the thrombosed vessel may become organized and a rare cure result, or a later recurrence of the aneurysm may be found. Gradual stretching and absorption of ligaments and erosion of bone may proceed until the aneurysm ruptures externally into soft tissues or into the knee joint. This complication is a constant and serious menace in any case of this disease.<sup>12</sup>

The first symptoms noticed may be those of interference with moving the knee, complete flexion or extension becoming especially difficult and painful. There may be a slight dragging sensation in the leg for months, with no other symptoms. Mechanical interference with venous return results in edema. In a high percentage of cases, pressure on the adjacent popliteal nerve is productive of numbness and pains of varied severity and location. They may be quite deceiving and give no indication as to their source, as in the case of McKenna.<sup>13</sup> The demonstration of a popliteal mass with expansile pulsating walls and a loud bruit is diagnostic. Vascular tumors must at times be excluded. This is most satisfactorily accomplished by arteriography.<sup>14</sup>

Before the advent of modern surgery, hemorrhage and gangrene were feared in every case of popliteal aneurysm, and amputation was the only treatment. Hunter and Desault in 1785 both practiced proximal ligation and thus later became the widely accepted form of therapy. In brief, the present day management consists in promoting collateral circulation and testing the efficiency of this circulation, then surgical exploration and selective correction, followed by further stimulation of circulation.

Special clamps and methods have been devised by means of which occluding pressure can be exerted on the cardiac pole of the aneurysm. According to Matas,<sup>15</sup> Baker<sup>16</sup> and others, repeated systematic occlusion aids greatly in increasing collateral circulation. The application of metallic bands directly to the artery, producing partial occlusion above the diseased area, has

been used by Matas<sup>15</sup> and Reid<sup>16</sup> with success. Lately sympathectomy as a preliminary has been advised by Bird,<sup>17</sup> Mulvihill and Harey<sup>18</sup> and Gage.<sup>19</sup> Passive vascular exercise or similar methods for the production of rhythmic positive and negative atmospheric pressures on the affected part have strong supporters.<sup>20</sup> The vasodilatory effect of whirlpool baths with warm water or of diathermy<sup>21</sup> may very well have a place in the treatment of popliteal aneurysms. In a study of 100 cases of sudden occlusion of the arteries of the extremities, McKeechne and Allen<sup>22</sup> advise three important "don'ts" in the treatment of these cases: "Don't delay treatment for more than two or three hours, don't elevate the extremity, and don't subject it to heat which exceeds by more than a few degrees the temperature of the body." The extremity should be protected from drying by bandages when heated under a cradle or by other forms of dry heat. Opiates, alcohol and papaverine hydrochloride may relieve pain and increase peripheral circulation.

Matas<sup>23</sup> stresses four methods of testing the efficiency of collateral circulation: (a) the hyperemic reaction or modified Moszkowicz color test, (b) the preliminary occlusion of the main artery close to the proximal pole of the sac with phlebotomy and removable bands, (c) oscillometric manometry to determine peripheral blood pressure after temporary occlusion of the main artery, (d) clinical evidence of a persistent circulation and nutrition of the peripheral parts in spite of permanent absence of peripheral pulses.

After the preliminary stimulation of collateral circulation and satisfactory evidence of its sufficiency, a careful exploration of the aneurysm is indicated in the hope of performing a restorative or reconstructive type of operation particularly applicable to saciform and certain traumatic cases in which a large portion of the circumference of the artery wall is in good condition. In other cases obliteration, ligation at one or both poles or ligation with excision is practiced. The most widely approved Matas<sup>24</sup> approach of endo-aneurysmorrhaphy has given the most excellent results. Here the vessel is entered the communicating lumens are sutured closed and the aneurysm is obliterated by plication.

#### REPORT OF CASE

A white man aged 64 married, a book auditor, admitted to the Bethany Methodist Hospital suffered with a severe continuous pain in the left calf and popliteal space. Four years before he had stepped off a rather high platform landing heavily on his feet and experiencing pain in the left calf and popliteal space. The pain recurred rather severely the next day and lasted several weeks during which time he limped about. This incident had been forgotten and he had noticed no discomfort or disability except for pains in the calf muscles associated with excessive walking and relieved by a few minutes rest. Suddenly, one day after he left his car and started up steps there developed a most severe pain in the

lower left popliteal area. There was a numbness and tingling in the unusually white, cold foot. Two quarter-grain (0.016 Gm) doses of morphine were necessary to ease the excruciating pain.

He was found to be in excellent physical condition except for the leg. This was cold from the knee down there was a loss of sensation of pain in the foot and an area of hyperesthesia was found in the upper half of the lower leg. No pulsations were found in the popliteal, anterior or posterior tibial arteries on the affected side. In the same arteries on the right side the pulsations seemed weak. Nothing unusual was felt or heard in either popliteal space. Popliteal thrombosis resulting from arteriosclerosis appeared certain.

In spite of complete rest local heat and dependence of the limb there developed a dry gangrene resulting in a sharp line of demarcation just below the head of the fibula by the seventh day following the onset.

The temperature rose slightly, from 99.4 F to 100.4 F during this period. There was also a slight elevation of pulse rate from 88 to 100 per minute. The respiration rate remained normal. The blood pressure at the onset was 220 mm of mercury systolic and in a few days varied from 120 to 140 systolic and 90 diastolic. There was a constant mild leukocytosis of 13,500 white blood cells with 80 per cent neutrophils. The red blood cell count and hemoglobin as well as blood chemistry and Wassermann tests gave normal results. A few granular casts and a one plus albumin were constantly found in the urine. An electrocardiogram tracing was interpreted as showing left ventricular preponderance but no graphic evidence of serious myocardial damage.

Two thrombosed popliteal aneurysms

A mid thigh amputation on the eighth day was followed by an uneventful convalescence except for the development on the eighth postoperative day of pain and rales in the lower left portion of the chest with a temperature of 101 F and no change in respirations or cough. This complication subsided in a few days. The amputation stump had healed rapidly and completely and he was discharged on the twentieth postoperative day.

In brief the pathologist's examination revealed the shriveled dry hard black toes soles and lower dorsal region of the foot with a dry hard gray-blue mottled lower leg below a line of demarcation in the middle upper third. The thrombosed popliteal artery had two aneurysms as shown in the accompanying illustration. The smaller at the upper end measured 3.5 cm long and 2.6 cm in diameter while the larger at the lower extreme measured 7 cm long and 3.7 cm in diameter. The aneurysms could be definitely palpated because of their size and position being partially hidden by muscles. The popliteal vein and nerve were closely adherent to the aneurysmal sacs. Small arteries entering both sacs were thrombosed. The femoral artery contained a loose dark red clot and had many small atheromas along its intima. The two tibial arteries were patent and had almost normally flexible moderately sclerotic walls.

Microscopic sections from the aneurysmal walls showed extensive arteriosclerotic changes with hyalinization of the thickened intima and inner portion of the muscularis also rather frequent deposits of cholesterol crystals and calcium in these hyalinized areas. Fat stains revealed an extensive fatty degeneration extending from the intima out and in places tiny fat droplets filled the cytoplasm of cells through the entire breadth of the muscularis. Elastic stains showed a marked paucity, granularity and fragmentation of elastic fibers especially in regions in which hyalinization and fatty degeneration were most extensive.

## SUMMARY AND CONCLUSIONS

The relative frequency of popliteal aneurysms, their often rapid progression, the disastrous gangrene in unaided cases and the efficacy of proper management makes this an important subject for every physician who is likely to encounter the condition. The near hopelessness of an untreated case in which sudden thrombosis develops is illustrated in the case of popliteal aneurysm the result of arteriosclerosis with a probable factor of trauma.

## EXPERIENCES IN THE SUMMER EPIDEMICS OF ACUTE ENCEPHALITIS IN TOKYO

HIROTOSHI HASHIMOTO, M.D.

MASASHIRO KUDO, M.D.

AND

KENJI URAGUCHI, M.D.

Senior Physician, Bacteriologist and Assistant Physician, Respectively  
of St. Luke's International Hospital

TOKYO, JAPAN

Outbreaks in the summer and early fall of an acute febrile disease with peculiar meningitis-like symptoms and a high mortality rate have long been known in Japan. In the epidemic of 1919 a few years after the reports of epidemic (lethargic) encephalitis in Vienna had come from Economo, medical men and neurologists in Japan first realized that they had been dealing with a type of acute encephalitis differing in seasonal incidence and clinical manifestations from epidemic encephalitis common in Europe. In 1924 there was a widespread epidemic in Kagawa and other provinces, the largest one ever recorded, in which extensive clinical and pathologic investigations were carried out. Occurrence during the summer, abrupt onset with high fever, stormy course with meningitic as well as encephalitic symptoms, and only occasional, transient, ocular manifestations, rapid recovery leaving few residual effects such as parkinsonism and a striking increase in both incidence and fatality rates with advancing age were mentioned in the reports as characteristic features distinguishing the Japanese type from the so-called "European form." Kaneko and Aoki<sup>1</sup> classified the prevailing type as type B to distinguish it from type A or the Economo type. Futaki called it "summer encephalitis," differentiating it from the epidemic encephalitis of Economo. Takaki,<sup>2</sup> by transmission of the disease to rabbits, isolated strains of virus which he called "virus of encephalitis japonica" differentiating it experimentally from the various herpes encephalitic viruses.

The epidemic encephalitis occurring in St. Louis and Kansas City during the summer of 1933 has recently been reported by Hempelmann,<sup>3</sup> McCordock,<sup>4</sup> Lenke,<sup>5</sup> and others as quite similar to the Japanese B type in clinical, pathologic and epidemiologic features. This information seems to conflict with the erroneous contention of some authors that the Japanese B type is unique in Japan. The results of etiologic investigation

of Webster<sup>6</sup> and others have been very helpful in throwing light on the work of our scientists, who have been continuing their investigation of the etiology of epidemic encephalitis in Japan.

It is of interest here to note that during recent epidemics in Japan we have encountered some cases of the Japanese B type encephalitis in Europeans and an American, in concomitance with many other cases in Japanese inhabitants of Tokyo City. In the summers of 1929 and 1930 when a considerable number of acute cases of encephalitis occurred among Japanese, a Spaniard and a Russian afflicted with the B type were admitted to St. Luke's International Hospital. They both recovered within a month, showing no evidence of residual nervous damage. Toward the end of August 1935 there occurred a sudden outbreak of the same type of encephalitis, to the great surprise of medical practitioners as well as inhabitants of the metropolis, with 1,362 cases reported in this city by September 10. With the morbidity rate not more than 22 cases per hundred thousand of population, and the mortality rate less than 30 per cent, this epidemic has generally been regarded as much milder than the heaviest one of 1914 in Kagawa. Nevertheless, it has received special attention from clinicians and medical scientists of the city, as it was the first opportunity for them to observe closely as many cases at one time occurring near by or admitted to their own hospitals or medical institutions. To St. Luke's International Hospital we admitted two Russians and an American. The two Russian patients after stormy courses both died within a week and the clinical diagnosis was verified by autopsy. The American, who showed a mild but typical clinical picture, is now convalescing.

All our patients were adults in the third or fourth decade of life. In three of them, who recovered, the onset of the illness was rather abrupt, with high fever, severe headache and meningitic or encephalitic symp-

Fig. 1.—Perivascular accumulation of mononuclear cells in the thalamus of a Russian patient who died with the Japanese B type encephalitis in Tokyo, Sept. 2, 1935. Positive mouse test.

toms, while in two fatal cases the initial rise of temperature was gradual, as in typhoid, without showing any evidence of involvement of the nervous system. These patients died within two days after typical clinical pictures of encephalitis had developed.

Early diagnosis in such cases is difficult. Among neurologic symptoms, neck rigidity, marked trismus,

rigidity of arms and occasionally also of legs with exaggerated tendon reflexes or with occasional transient paralysis, tremors of the tongue and hands, mental confusion, mental apathy and speech disturbances of aphasic nature were common in all cases. There was no ocular manifestation other than photophobia in two or three cases and transient unilateral ptosis of the eyelid in one case. The Kernig sign or Babinski reflex

logically there were perivascular accumulations of mononuclear cells (fig 1), small focal collections of mononuclear cells with a few polymorphonuclear cells and degeneration of nerve cells in basal nuclei, pons and medulla. Also in the meninges there was an infiltration of mononuclear cells.

The clinical and pathologic manifestations in foreign patients with encephalitis were all comparable to those of many Japanese cases encountered during the same epidemics in this city. As a result of our experiences in the recent epidemic in Tokyo, we feel that we have further evidence that no clear distinction can be made between the Japanese B type and the reported St. Louis type.

With regard to etiologic factors, very little has been known concerning Japanese epidemic encephalitis. A long continued exposure to the direct effects of sunlight, mental or physical fatigue in hot weather and like causes have been blamed as contributing etiologic factors in ushering in the illness. But as the recent epidemic continued through cooler weather, the foregoing factors could not be held responsible for the onset of illness in many cases.

So far as the infective agent is concerned, we are now undertaking experimental studies according to those reported by Webster and others<sup>6</sup> of the St. Louis epidemic, which gave such successful results.

In our laboratory, Kudo and Uruguchi have inoculated mice intracranially, intranasally and intraperitoneally with brain emulsions obtained from three fatal cases in the hospital. The brain tissue was removed aseptically from the bodies kept overnight in the morgue, preserved in glycerin for from two to ten days in the icebox and then emulsified. The mice used for the experiments were white mice of the strains called German mice, available in this city. The emulsions of brain tissue were diluted with physiologic solution of

Fig. 2—Perivascular accumulation of mononuclear cells in the thalamus of a Japanese patient who died with the Japanese B type encephalitis in Tokyo, Aug. 27, 1935. A specimen from the same patient was used for the first successful transmission of the disease to mice.

was only occasionally demonstrable. Retention of urine or incontinence of urine and feces was present in two fatal cases.

Concerning the clinical course, the temperature, having reached a maximum exceeding 104 F, which occurred somewhat earlier than the fifth day of the disease, began to fall by lysis and in three cases reached normal within ten days of the onset. In one of these there was a secondary rise of temperature of the remitting type, which lasted for a week. This was not attended by aggravation of neurologic symptoms and was attributed to a pulmonary complication. These three patients recovered with few residual effects. Two patients died with severe respiratory failure within two days of encephalitic manifestations when the temperature tended to fall. The deaths occurred on the fifth and the seventh day of the illness.

The spinal fluid examined at the height of the disease was clear under moderately increased pressures showing moderately increased cell counts with mononuclear preponderance. In one of the fatal cases 72 per cent of 232 cells were found to be polymorphonuclear leukocytes in fluid obtained one day after the encephalitic symptoms set in with convulsive attacks. The patient died within a day after this test. Blood examination revealed moderate degrees of leukocytosis in all but one. In one fatal case not the one just mentioned, there was no leukocytosis although the blood was examined when the patient had a fever. The Schilling hemogram however showed a definite shift to the left. Bacterial cultures of blood and spinal fluid were all negative.

At autopsy the meninges were found to be edematous with a moderate increase in amount of the cerebrospinal fluid and with marked congestion of blood vessels. Cross-sections through the brains revealed obvious congestion of intracerebral blood vessels with pinkish discoloration of the gray substance of the cerebral cortex as well as basal nuclei or pons. Histo-

Fig. 3—Perivascular accumulation of mononuclear cells in the brain of a mouse that died showing characteristic encephalitic manifestations five days after the transmission of the disease from an infected mouse.

sodium chloride to about 10 per cent of which 0.03 cc was injected intracerebrally and from 0.2 to 0.5 cc intraperitoneally into each mouse.

The first patient from which the brain tissue was used was a Japanese woman aged 58 who had shown a clinical picture characteristic of Japanese B type encephalitis. She died in the hospital after four days on Aug. 27, 1935. The clinical diagnosis was verified by autopsy (fig 2). Brain tissue was preserved in glycerin for two days before it was emulsified. Follow-

ing combined intracerebral and intraperitoneal injections into twelve mice, they all remained apparently healthy for from four to seven days and then became hyperesthetic, showing first ruffled fur and then tremors, convulsions and peculiar motor disturbances, followed by prostration and death in from six to nine days.

Perivascular accumulations of mononuclear cells histologically demonstrable in their brains were comparable to those in the human brain. The brain tissue from infected mice was further inoculated by the same technic into the second series of healthy mice. These specimens proved bacteria free in aerobic and anaerobic cultures. After a three or four day incubation these inoculated animals also developed tremors, occasional convulsions, hyperesthesia and prostration and died in four or five days. Characteristic lesions were also found histologically in their brains (fig 3).

Transmission of the disease from infected mice to healthy mice has been so far successfully carried through five successive series without any apparent decrease in the response to the inoculation. Berkefeld N candle (prodigiousus-fast) filtrates of brain tissue emulsions from the infected mice as well as the aforementioned human specimen have proved as readily infective as the original emulsions. Specimens of brain tissue secured from two Russian patients were also inoculated into mice after they were preserved in glycerin for six and ten days respectively. With the six day glycerinated specimen, transmission was successful, seven of nine inoculated mice dying in from five to eight days, and one in fourteen days. On the second transmission of the disease animals died in from four to seven days. The third transmission also was successful. The series of animals into which the ten day glycerinated specimen was inoculated were still alive after more than two weeks, showing no response. Control tests with brain tissues obtained from healthy mice or from human patients who had died of other diseases were all negative.

Further investigations are now being conducted to determine whether or not the infectious agent thus isolated can be neutralized by serum of individuals convalescent from the encephalitis of the recent Tokyo epidemic. We have already secured a positive evidence for it. To establish this point, however, we shall have to await completion of the experiment.

As we have demonstrated experimentally that in the recent epidemic in Tokyo the disease can be easily transmitted from fatal cases of encephalitis to mice and from mice so infected to successive series of healthy mice, and that the infectious agent thus obtained traverses Berkefeld N candles we have been inclined to infer that the so-called Japanese B type encephalitis and the St. Louis type are similar, not only in clinical or anatomic characteristics but presumably also in the biologic nature of the infectious agent.

#### SUMMARY

In the recent epidemics of encephalitis in Tokyo the Japanese B type occurring in occidentals was found to be similar in all respects to that contracted by the Japanese.

In the recent outbreak of encephalitis in Tokyo, the transmission of the disease to mice was found to present no difficulties, agreeing with the experience in the 1933 St. Louis epidemic.

The Japanese B type and the St. Louis type are alike not only in their clinical and pathologic features but also in etiology.

## Clinical Notes, Suggestions and New Instruments

### THE TREATMENT OF CHRONIC (TUBERCULOUS AND OSTEOMYELITIC) FISTULAS WITH SILVER NITRATE STICKS

ERNST FREUND M.D. VENICE, FLA.

In his paper on the formation and disappearance of amyloid in man, Waldenström<sup>1</sup> writes the following paragraph:

"When a patient is admitted to the hospital he is given a few weeks to get accustomed to his new surroundings. During this time his fistulas are washed once or twice daily with a solution of 1 per cent iodine in benzene. This is done with exceedingly great care. The surrounding skin is also carefully washed and a large sterile dressing applied. Should the fistulas subsequently prove to be too narrow, causing the pus to stagnate somewhere they are treated strongly with lapis. Should this prove insufficient a method is adopted which I believe very excellent. A stick of pure silver nitrate, about 6 cm. long, is inserted into the fistula its end coming just underneath the skin edges. The following day the stick is pulled out by a pair of forceps and accompanying it there comes out a rod of silver albuminate sometimes as thick as a finger, consisting of the tuberculated wall of the fistula, the granulations soon become healthy at this place."

This method appealed to me because of its simplicity and I tried it out in about twenty cases during the last year. First I limited it entirely to cases of chronic bone tuberculosis complicated by chronic fistulas. Later it was also tried in cases of chronic nonspecific osteomyelitis with sinuses, but roentgenologically without more active signs of bone infection. Healing of the sinus tract was not obtained in all cases but in a number the results were very satisfactory. In one case of chronic tuber-

Fig 1—Three sinus tracts incrustated by silver nitrate removed two or three days after insertion of silver nitrate sticks.

culous hip disease in which the surgical fusion was postponed for years because of a persisting sinus, the method proved especially beneficial. The sinus tract closed within a short time and fusion was performed without complications. I have not yet seen any damage from insertion of the silver nitrate stick. There is no resorption of silver in the feces or the urine. There were not even traces and only mild general symptoms. The first hour the patient complains of some burning sensation and headache and may even be a little restless the first night but all discomfort disappears next day.

I proceed in the following way. The sinus tract is probed to determine its caliber and direction. If it is narrow it is

From the Department of Orthopedic Surgery, State University of Iowa (Dr. Arthur Steindler).  
<sup>1</sup> Waldenström, Henning. On the Formation and Disappearance of Amyloid in Man. *Acta chir. Scandinav.* 63: 479 (Aug. 25) 1928.

enlarged very gently and gradually with a straight hemostat. The silver nitrate stick is then inserted slowly, always following the sinus tract. Care should be taken not to produce a false route. If the sinus tract is longer than the ordinary silver nitrate stick, parts or the whole length of a second stick can also be inserted. The skin is then covered by a thick layer of zinc oxide ointment in a wide area around the sinus tract and

Fig 2—Microscopic cross section through sinus tract after silver nitrate treatment. Concentric precipitation of silver nitrate albuminates in the peripheral layers of the fistula. Histologic structure is well preserved in the inner layers.

a sterile dressing is applied. There is considerable purulent discharge from the sinus tract and as a rule, despite the ointment, some irritation of the skin by the dissolved silver nitrate. If one tries to remove the silver nitrate stick after twenty-four hours, one succeeds only partially, and the patient complains of pain; the silver nitrate has dissolved but the sinus tract is not yet loose. In chronic sinuses it takes about two or three days before one is able to remove the entire tract. With a forceps one can easily remove the incrustated sinus tract which in some cases was more than 6 inches long and of the thickness of a little finger. Immediately after removal the tract is gray but turns black quickly if exposed to light. The remaining sinus tract is covered by nice, red, healthy-looking granulations. It is washed out with solution of hydrogen peroxide. The finger-thick canal very rapidly shrinks and the healthy granulations may lead to complete and permanent closure.

The histologic structure of sinus tracts that were removed could easily be made out. Quite frequently tubercles can be seen in the inner layer. The vessels, especially, are nicely visible because their walls show silver impregnation. There is a regular concentric precipitation of silver albuminates farther away from the sinus lumen. The inner layers show only fine granular diffuse involvement. The concentric arrangement is strikingly similar to the structure of gallstones or cartilaginous joint bodies in which also anorganic lime salts become precipitated in organic matter. It is an expression of the gradual diffusion of the silver salts and corresponds most likely to the

concentric rings described by Liesegang. In his colloid chemical studies Liesegang made the observation that the solid form of a not easily soluble substance becomes precipitated in gel not evenly but in layers. He explains the concentric arrangement of the layers with a rhythmic diffusion of the dissolved substance. The separation of the incrustated sinus wall takes place along the most peripheral ring or tube of precipitation. The histologic details of this process could not be examined because the zone of demarcation remains in the body.

My only purpose is to call attention to a method that is harmless and may often render good service in chronic sinuses.

Florida Medical Center

## PARADOXICAL EMBOLISM

ROBERT KORITSCHONER, M.D., KANSAS CITY, MO

From the Department of Pathology, Menorah Hospital

Statistics show a patency of the foramen ovale in approximately 33 per cent at all autopsies. Paradoxical embolism is the passing of a blood clot from the right to the left side of the heart through the patent foramen ovale. This possibility enables the pathologist to account for certain embolic phenomena. The explanation, however, is often questioned by the clinician. The incidence of an embolus passing through the

Fig 1—Right auricle with the embolus coiled up.

patent foramen ovale is not of great clinical importance but carries considerable pathologic interest. Only twelve cases of this type are found in the literature.<sup>1</sup>

1. The following include:  
Zahn, F. W. *Rev. med. de la Suisse Rom.* 1881, p. 227.  
Hauer, G. *München med. Wochenschr.* 25: 583 (1888).  
Polar, A. *Thec. de Genève* 1884 (three cases).  
Verne, Max. *Verhandl. d. deut. path. Gesellsch.* 17: 215 (1909).  
Thompson, T. and Evan, William. *Quart. J. Med.* 23: 155 (Jan. 1930) (two cases).  
Willing, M. *Z. f. Kreislaufsch.* 19: 505 (Aug. 1) 1927.  
Bernard, W. C. *Quart. J. Med.* 23: 305 (April) 1930.  
Taylor, James. *Paradoxical Embolism*. *Arch. Path.* 16: 901 (Dec.) 1935.  
French, I. R. *Paradoxical Embolism*. *Arch. Path.* 11: 383 (March) 1931.

The following case is reported because of its rarity

A woman aged 63 died six days after a uterine suspension. Her condition was satisfactory until the evening of the sixth day, when she collapsed and became dyspneic and cyanotic. She partially recovered but died suddenly three hours later. At autopsy a large well formed embolus, slightly adherent, was found in the main branch of the left pulmonary artery, and several smaller ones of the same character were demonstrated in the branches of the right pulmonary artery. The heart showed a long embolus which had been caught as it passed through the foramen ovale. The main portion lay coiled up in the right auricle. One end extended 1 cm into the left

Fig 2—Left auricle with the end of the embolus sticking through the foramen ovale

auricle. The origin of these emboli was traced to the right iliac and femoral veins where a roughness of the intima, without thrombus was demonstrated.

The clinical symptoms were evidently due to a massive embolus in the main branch of the pulmonary artery. As a result of the obstruction to the pulmonary circulation there ensued a marked increase in blood pressure in the right side of the heart which produced a dilatation and stretched the pre-existing small opening in the foramen ovale. The diminished pulmonary circulation decreased the pressure in the left auricle. Thus disturbed balance probably produced a condition which favored the development of a paradoxical embolism. It is conjectured that a second embolus was formed between the two attacks. This clot was probably released into the circulation and was lodged at the foramen ovale. The second embolus coiled up in the right auricle and completely obstructed the pulmonary circulation which caused immediate death.

**Too Much Digitalis**—The most frequent sign of too much digitalis is nausea and vomiting and when occurring they indicate cessation of the drug—Dr Henry Christian quoted by Fisher Alexander Aphorisms in Clinical Medicine *Canad J Med & Surg* 77 166 (June) 1935

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A CARTER Secretary

### DeFOREST DYNATHERM ACCEPTABLE (Types "M," "NE" and "D")

Manufacturer Lee DeForest Laboratories, Los Angeles

These short wave diathermy machines are recommended by the manufacturer for the application of medical diathermy and for electrosurgery. The chassis, construction and electrical circuits for the three models are identical. The difference between the three models is confined entirely to the construction of the cabinet. The weight of all three is eighty pounds.

Model "M" is encased in a heavy steel cabinet with steel panels.

Model "NE" is in a steel case and is in every respect identical to Model "M" with the exception that the instrument panel is of the sloping vertical type rather than the sloping horizontal type as is Model "M."

Model "D" embodies the same chassis and circuit except that it is encased in a suitcase type of cabinet for portability.

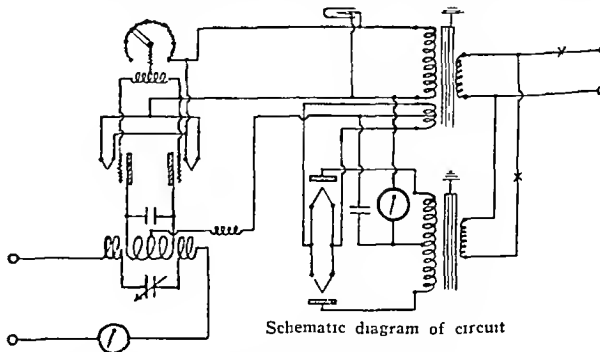

Models "M," "NE" and "D" make use of oscillating audion circuit employing four vacuum tubes—two for rectification and two for generating high frequency currents. The wavelength is 18 meters. These units operate from 110 alternating current circuit. Special additional equipment is necessary in case the physician's supply is direct current. The maximum power input for these units is approximately 1,000 watts.

Since there is no acceptable method for measuring the output of diathermy machines, this value is not stated. Operating the machine under full load indicated that the temperature rise of the transformer and the cabinet was within the temperature limits considered safe by the Council.

At the request of the Council the firm submitted data concerning the tissue heating efficacy of the machine when used on the human thigh. The results of the investigations showed that, when using the cuff electrode technique the temperature rise in the deep-lying tissue was higher than when using conventional diathermy—the criterion which the Council has adopted for investigating short wave machines—and these results were confirmed by the Council's investigator. Cuff electrodes are supplied as standard equipment. Furthermore pad elec-

DeForest Dynatherm Model M

Schematic diagram of circuit

trodes are also part of the standard equipment and the firm claims they are efficient applicators.

Burns may be produced by this machine but if ordinary care is observed they may be avoided. Their likelihood to occur is much less than when conventional diathermy is used.

The machine was used by the Council's investigator in a clinic for several months and he reported that it gave satisfactory clinical service. In view of the favorable report the Council voted to include the DeForest Dynatherm (Types "M," "NE" and "D") in its list of accepted apparatus.

# THE KANSAS CITY SESSION

AMERICAN MEDICAL ASSOCIATION, EIGHTY-SEVENTH ANNUAL SESSION

KANSAS CITY, MO., MAY 11 15, 1936

## OFFICIAL CALL

### TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The eighty-seventh annual session of the American Medical Association will be held in Kansas City, May 11-15, 1936

The House of Delegates will convene at 10 a m Monday, May 11 In the House the representation of the various constituent associations for 1935 1936 and 1937 is as follows

Alabama	2	New Hampshire	1
Arizona	1	New Jersey	4
Arkansas	2	New Mexico	2
California	7	New York	17
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	3
Florida	2	Oregon	2
Georgia	3	Pennsylvania	11
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	2
Indiana	4	South Dakota	1
Iowa	2	Tennessee	3
Kansas	3	Texas	6
Kentucky	3	Utah	1
Louisiana	2	Vermont	1
Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	6	West Virginia	2
Michigan	5	Wisconsin	3
Minnesota	3	Wyoming	1
Mississippi	2	Alaska	1
Missouri	5	Hawaii	1
Montana	1	Isthmian Canal Zone	1
Nebraska	2	Philippine Islands	1
Nevada	1	Puerto Rico	1

The fifteen scientific sections of the American Medical Association the Medical Corps of the Army the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each

The Scientific Assembly of the Association will open with the general meeting to be held at 8 p m Tuesday May 12 The sections will meet Wednesday, Thursday and Friday, May 13 14 and 15 as follows

#### CONVENING AT 9 A M THE SECTIONS ON

Practice of Medicine	Nervous and Mental Diseases
Surgery, General and Abdominal	Dermatology and Syphilology
Ophthalmology	Gastro-Enterology and Proctology
Pharmacology and Therapeutics	Radiology

#### CONVENING AT 2 P M THE SECTIONS ON

Obstetrics, Gynecology and Abdominal Surgery	Pathology and Physiology
Laryngology Otology and Rhinology	Preventive and Industrial Medicine and Public Health
Pediatrics	Urology
	Orthopedic Surgery

Miscellaneous Topics Session on Tuberculosis

The Registration Department will be open from 8 30 a m until 5 30 p m Monday Tuesday Wednesday and Thursday May 11 12, 13 and 14, and from 8 30 a m to 12 noon Friday May 15

JAMES S MCLESTER President  
NATHAN B VAN ETEN Speaker House of Delegates  
OLIN WEST Secretary

## MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included

## KANSAS CITY, 1936—THE HEART OF AMERICA

The ruddy vigor enterprise and enthusiasm of the great Southwest, combined with the beauty and cultural achievements of the East, make Kansas City truly The Heart of America.

Trading posts were founded early in the nineteenth century by Indian trappers and fur traders who paddled their canoes to the junction of the Kaw and Missouri rivers where Kansas City now lies. Fur traders were followed by agricultural pioneers by the middle of the century a newspaper, telegraph and postoffice were established. Pioneer villages then known as Westport and Independence had become outfitting posts for the caravans that crossed the West. The famous Santa Fe trail had its inception within the present city limits. Stimulated by the steamboat trade, Kansas City rapidly became the logical distributing point for the great Southwest.

Today Kansas City blends the culture of the East, the vision of the West, the energy of the North and the hospitality of the South. Proud of the beauty and extent of its cultural achievements, Kansas City's modern Municipal Auditorium, new Jackson County Court House, Power and Light Building, United States Post Office, William Rockhill Nelson Gallery of Art, Liberty Memorial and unsurpassed boulevards and residential districts are all concrete evidence of the good taste and artistic appreciation of this agricultural empire.

### THE AUDITORIUM

The American Medical Association is fortunate in being among the first to enjoy the new \$6,000,000 Municipal Auditorium. Located in the heart of downtown Kansas City within two to five blocks of almost all hotels, the new auditorium is a tribute to modern architecture.

Complete air conditioning and mechanical ventilation assure controlled and uniform temperatures within regardless of prevailing weather conditions. This is made possible by the third largest air conditioning system in the country, the system installed in the auditorium being exceeded only by those in the department of commerce building and the postoffice department building in Washington.

The main arena seating from 13,000 to 15,000 resembles a huge amphitheater or stadium and its lighting and acoustic properties are said by engineers to be the finest in the country.

Modern even to its color scheme of rich yellows, rusts and blues, the exhibition hall affords some 90,000 feet of space while foyers and arenas increase this area by 60,000 additional feet.

Two small theaters seating 3,500 and 1,200 and thirty-three committee rooms accommodating groups of from twenty-five to a hundred all of which may be placed in direct communication with the main arena by use of the high fidelity public address system make the hall readily adaptable to any meeting requirements.

### ACTIVITIES OF THE JACKSON COUNTY MEDICAL SOCIETY

Since 1881 the Jackson County Medical Society has been the guide and translator of all things medical in Kansas City.

Through the untiring effort of early members of the society the necessary bond issue was initiated and passed for the establishment of a municipal hospital. Interested obstetricians later stimulated the establishment in the General Hospital of an antepartum clinic which now serves some thirty patients daily and has greatly reduced fetal and maternal mortality.

The Kansas City medical profession is ably represented in the educational field, many widely known teachers and writers coming from their ranks. Such writings have been widely used in army medical units translated into many languages and used as textbooks throughout the world. Others have written extensively on such special fields as pathology, dermatology, congenital syphilis, focal infection and allergy, posture or child health.

The Jackson County Medical Society is justly proud of its library. This library after long discouraging hard years of labor on the part of an interested few, now represents one of the largest collections owned by a county society in the United States.

### KANSAS CITY SOUTHWEST CLINICAL SOCIETY

Kansas City's Southwest Clinical Society is among the pioneers in its plan of organization for a method of promoting postgraduate medical education. It was organized in 1922 with a limited membership of surgeons, internists and specialists of Greater Kansas City. This society mimeographs a daily bulletin of the operations, ward walks and clinics at eleven allied grade A hospitals in Greater Kansas City. It conducts the annual fall clinical conference during the first full week in October with at least ten distinguished guests and scientific and technical exhibits. Its membership promotes monthly hospital clinics at one hospital each month on the second Tuesday and combines with the Jackson County Medical Society for the evening program on the same day. It also publishes a monthly bulletin which is distributed to 6,200 physicians of Kansas City and surrounding territory. This bulletin carries the papers read by distinguished guests and members of the fall conference and monthly hospital clinics.

Since 1933 the society has conducted a spring medicomilitary symposium for two days during the second week in March in conjunction with the eighth army corps area and naval reserve authorities open to all physicians and required for army and navy reserve officers. An office with a full time executive secretary is maintained at 205 Shukert Building, 1109 Grand Avenue.

THE CITY HALL NOW UNDER CONSTRUCTION

## KANSAS CITY PUBLIC HEALTH DEPARTMENT

The Jackson County Medical Society has continued to develop power and influence during its fifty-four years of existence until it now virtually dominates the health policies of the community it serves. The Kansas City Department of Health enjoys the counsel and complete cooperation of its membership.

Kansas City for the past ten years has operated under the city manager type of government. Under the direction of Dr. Edwin Henry Schorer, the work and organization of its health department differs somewhat from that of most cities.

The director's office, the personnel, vital statistics, communicable diseases and child hygiene divisions are located at the city hall. All the other activities except the Municipal Tuberculosis Hospital are on what is known as 'Hospital Hill' and include the divisions of laboratories, inspection, sanitation, municipal hospitals, ambulance and motor vehicles maintenance and repair and the central service station.

The municipal hospitals are General No. 1 for the white, General No. 2 for the colored and the tuberculosis and isolation

RETAIL SHOPPING DISTRICT IN KANSAS CITY

hospitals for the white and the colored. The staffs of the general hospitals are voluntary. 165 at the hospital for the white where only members of the Jackson County Medical Society are eligible and forty-one at the hospital for the colored where only physicians belonging to the Jackson County Medical Society or the Kansas City Medical Society (colored) are eligible.

The salaried personnel of the health department numbers 484 for General Hospital No. 1, 186 for General Hospital No. 2, 151 for the Tuberculosis Hospital and 142 for all other departments. General Hospital No. 1 has 400 beds, General Hospital No. 2, 208, Isolation Hospital for the white, seventy, Isolation Hospital for the colored, forty-two, and the Tuberculosis Hospital, 213 beds for the white and forty-seven for the colored.

The annual appropriation for the health department amounts to about 20 per cent of the general fund revenue, which is quite liberal since the health department cooperates only on sewage disposal, collection of garbage and the production of the water supply.

The Tuberculosis Hospital at Leeds is one of the few municipal hospitals for the treatment of tuberculosis. It has a completely modern surgical pavilion, which has been completed within the last year. Cases are transferred from the state and county sanatoriums for surgical treatment. The operations most often performed are phrenicectomy, thoracoplasty, pneumolysis and plumbage. Patients are admitted through the tuberculosis service in cooperation with the Kansas City Tuberculosis Society, and the hospital's combined plant has been checked by many of the country's foremost phthisiologists and proclaimed a complete and modern working unit for the treatment of all types of pulmonary tuberculosis.

Outpatient departments are maintained at both of the general hospitals and a social service department is included which cooperates with the Council of Social Agencies. All patients except some at the Tuberculosis Hospital are registered at the Central Index of Indigency.

At all the municipal hospitals and outpatient departments there are dental services operated by members of the staff selected from the membership of the Kansas City Dental Society.

In no instance does the health department concern itself with diagnosis. In every instance where possible, it provides the materials prescribed by the professional staff.

## HOSPITALIZATION

Greater Kansas City has twenty-six hospitals with a bed capacity of 3,279. Of these, twenty-one are in Kansas City, Mo., and five in Kansas City, Kan. Included are:

Hospital	Under Auspices of
Neurological Hospital	Eleemosynary corporation
Children's Mercy Hospital	Association
Memorial	Association
Evangelical Hospital	Evangelical Deaconess Society
Farmount Maternity Hospital	Privately owned
Florence Crittenton Home	Women's Interdenominational Missionary Council
Colored Hospital (public)	City of Kansas City
General Hospital (public)	City of Kansas City
K. C. Industrial Hospital	Privately owned
Tuberculosis Hospital (public)	City of Kansas City
Lakeside Hospital	Privately owned
Research Hospital	Association
St. Joseph's Hospital	Sisters of St. Joseph
St. Mary's Hospital	Sisters of St. Mary
St. Luke's Hospital of Kansas City	Episcopal Diocese
St. Vincent's Maternity Hospital	Catholic Diocese
Trinity Lutheran Hospital	Augustana Lutheran Synod
The Willows Maternity Sanitarium	Privately owned
Vineyard Park Hospital	Privately owned
Wesley Hospital	Privately owned
Whitely Provident Hospital (colored)	Association
Kansas City, Kan.	
Bell Memorial Hospital (public)	State of Kansas—University of Kansas Medical School
Doughless Hospital (colored)	African Methodist Episcopal Church
Providence Hospital	Sisters of Charity
St. Margaret's Hospital	Sisters of St. Francis

Kansas City's Mercy Hospital, an outgrowth of the determination and untiring effort of Dr. Katherine B. Richardson, is as important to Kansas City as Jane Addams and Hull House to Chicago.

Handling more than 22,000 children a year who are unable to pay a dollar for their care, the cornerstone of the new million-dollar Mercy Hospital bears the inscription: In 1897 Dr. Alice Berry Graham founded this hospital for sick and crippled children to be forever non-sectarian, non-local and for those who cannot pay. Founded on the ideals of Dr. Graham and her sister Dr. Richardson, Mercy had its beginnings in their home—first as one bed, then a house of a few rooms, then a larger house, followed by a bigger brick hospital on Highland Avenue—and then the beginnings of the present hospital at Independence and Woodland Avenue. With its growth in size, expenses mounted, and following Dr. Graham's death in 1913 it was only Dr. Richardson's genius in planning and in raising money and her executive ability in organization that made it possible to continue. Like an itinerant preacher she journeyed each Saturday to some neighboring town in Kansas City territory, never asking for money but explaining the purposes, ideals, equipment and organization of Mercy to the leading women in that town. Today, as a result, some 300 Mercy hospital clubs in 300 neighboring towns and villages send thousands of chil-

dren and, seeing the work being done lend their support. Donations from this source have amounted to as much as \$15,000 annually. So for thirty-nine years Dr. Richardson and her efficient superintendent Anna A. Anderson with a staff of twenty-five of the finest physicians and surgeons in Kansas City, have donated their services to the children of the poor. The afflicted ailing, crippled, deformed, abnormal and neglected have all found a haven at Mercy. In recent years Mercy has received a share of the money raised in the annual charity drive and today finds it entirely free from debt and prospering on the ideals and spirit built into it by its courageous founders.

Another Kansas City hospital of national interest is the clinical branch of the University of Kansas School of Medicine. Located two miles southwest of the Municipal Auditorium at Thirty-Ninth and Hudson Road, it occupies a new site on the Kansas side of this metropolitan area. The newly developed medical plant is situated on a beautiful and slightly location occupying fifteen acres of land and now composed of a group of four new buildings of modern construction including Bell Memorial Hospital, the Nurses Home, the Medical School and the Power Plant. New units now under construction include the children's pavilion, the new clinic building or outpatient building, and the research laboratory. The last unit mentioned is to be known as the Hixon Laboratory for Medical Research.

The first year and a half of the medical course is given at the University of Kansas at Lawrence forty miles west of here where the departments of anatomy, physiology, biochemistry and

general medicine and surgery and orthopedics, with complete x-ray and laboratory equipment. Wesley Hospital offers special x-ray equipment for high voltage therapy.

The services of a full time pathologist at Bethany Hospital place immediate frozen section, tissue and necropsy work at the disposal of physicians. This hospital is also fully approved by the Crippled Children's Commission for treatment of children with orthopedic conditions and congenital cataract.

In addition to Providence and St. Mary's hospitals, which are general hospitals equipped to do general work, Kansas City is proud of its new Menorah Hospital, opened in 1931. Menorah is well known for its cancer clinic, having \$10,000 worth of radium. Here also is the most completely equipped physical therapy department in Kansas City.

St. Vincent's Maternity hospital operated by the Catholic Sisters of Charity of St. Vincent de Paul specializes in obstetrics exclusively. The Neurological Hospital or Robinson Clinic is an eleemosynary corporation founded in October 1936 and it limits its cases to nervous and mental illnesses, alcoholism, narcotics and allied conditions. It has an open staff and the facilities of the former Christian Church Hospital have been remodeled to adapt the building to the particular needs of this specialty and provide sufficient inside recreational space. Special type steel casement windows obviate the necessity of bars and heavy screens, and recreational facilities include game rooms, a music room, theater and auditorium, roof garden, individual and hall radios, scientific and popular library, gym

THE KANSAS CITY GENERAL HOSPITAL

bacteriology are located. The last two and one-half years are given in the Kansas City Division of the Medical School. The clinical branch of the Medical School was first organized in 1905 through the amalgamation of four schools in this district and one located in Topeka. It was started by Dr. Simeon Bell who presented the university eight acres of land and erected a laboratory and teaching building for the use of the Medical School in Rosedale, Kan., formerly a suburb of Kansas City, Kan., and a part of the metropolitan area of Greater Kansas City. In 1924 this original site was considered unsuited for the development of a new medical center and a new site composed of fifteen acres located one mile south of the old location was secured. At this place three units are now completed and four additional ones are in the course of construction.

The University of Kansas Hospitals, the main unit of which is known as Bell Memorial Hospital, have at present a capacity of 250 beds and are owned and controlled by the Medical School. Eighty-five per cent of the beds are available for teaching purposes in spite of the fact that the hospital is 80 per cent self-supporting. The outpatient department serves patients from either side of the state line and the attendance exceeds 70,000 visits annually. The departments of pathology and pharmacology are still located at the old site one mile away but will be moved to the new location as soon as the new buildings are ready for their accommodation.

St. Joseph's Hospital has a well equipped physical therapy department, x-ray department and approved clinical pathological laboratory and obstetric department.

Research Hospital has one of the most complete diagnostic clinics in this section. St. Margaret's hospital in Kansas City, Kan., offers a research fellowship under the Boylan endowment fund. Its departments include pediatrics, obstetrics, urology,

nasium, occupational rooms and ample provision for outdoor sports.

Wheatley Provident Hospital for the colored specializes in eye, ear, nose and throat work, has all the standard laboratory equipment, and is one of the few hospitals for Negroes to receive an A rating.

#### DENTAL EDUCATION

Dental education in Kansas City was first established with the organization of the Kansas City Dental College in 1881, the Western Dental College being established nine years later.

These two schools were united in 1919 as the Kansas City Western Dental College, and the charter of the new organization established the school on a strict educational basis, divorcing it from all commercial interests. In 1923 a large new fireproof building was erected and the most modern equipment purchased, placing the school among the first ten of some forty comparable colleges and entitling it to an A rating by the Dental Educational Council of America.

Through the generous bequest of Dr. Howard S. Lowry, the college was enabled to establish three internships in children's dentistry and receives approximately 200 children each week in its free clinic, the patients being selected from the public schools by visiting nurses.

Another gift of \$27,000 was made in 1935 which was used to purchase 300 oral surgery models which constitute a visual education in this field.

With nine full time instructors, the enrollment of the Kansas City Western Dental College ranks fifth in the United States. There have been about 4,000 graduates since its inception fifty-five years ago and its students include representatives from practically all states of the Union and some foreign countries.

## SPECIAL GROUPS

Officers and members of various examining boards and sections of the American Medical Association will be interested in the meetings of Kansas City's special groups including the Kansas City Academy of Medicine, Kansas City Dermatological Society, Kansas City Obstetrics and Gynecology Society, Kansas City Society of Ophthalmology and Otolaryngology, Kansas City Society of Pathologists, Kansas City Society of Pediatricians and the Kansas City Urological Society. These special interests hold weekly bimonthly or monthly meetings for the purpose of studying interesting clinical cases, conducting special courses of instruction or entertaining guest speakers of special prominence in their particular fields.

CULTURAL AND RECREATIONAL  
FACILITIES IN KANSAS CITY

More than a hundred miles of beautifully landscaped drives at the height of their beauty in the late spring season await the convention visitor.

Cliff Drive to the northeast of the city retains the natural scenic beauty and charm of a winding drive through the mountains with Budd Park inviting relaxation and an occasional distant view of Kansas City serving as a reminder of midwestern enterprise.

Restful Penn Valley to the south home of The Scout and A. Phimster Proctor's sculptural group. The Pioneer Mother forms a picturesque link between down-town Kansas City and its outlying shopping areas.

When seen after night the Liberty Memorial is a sight of majestic power and a battery of blue lights directed on a series of fountains presents a kaleidoscopic picture of mystical beauty with all Kansas City's vast skyline unfolding when viewed from this 537 foot height. All this however is in sharp contrast to the wealth of war trophies, weapons, communications and factual information contained within the memorial, a collection that merits several hours of browsing.

Ample opportunity for outdoor sports is afforded in Kansas City's Swope Park—the third largest municipal playground in the world. Its 1,400 acres of rustic woodland, three golf courses, tennis courts, picnic grounds, shelter houses, natural footpaths, outdoor animal pits, zoo and lagoon for swimming and boating afford interest and entertainment for groups of all ages and tastes.

It has been said that the index to any city may be found in its homes. If this is true, a few hours spent in exploring Kansas

City's country club district justifies its claim to the most important high type residential development in the world, and the largest contiguous restricted district to be found in the United States.

Served by the Country Club Plaza, ever seasonable and festive in its decoration and Spanish in its architecture, this outlying shopping area constitutes a complete and beautiful miniature city in itself, served by its own residential parks, golf course, playgrounds and shopping centers.

Those with cultural interests will want to explore the building and grounds of Kansas City's rapidly growing five year old

University of Kansas City and feast on the spacious grounds and classic architecture of the William Rockhill Nelson Gallery of Art.

Made possible by the bequests of William Rockhill Nelson, the founder of the Kansas City Star, the gallery is erected on the grounds of Mr. Nelson's former residence, Oak Hill, and the dignity and scientific construction of the building itself bespeak the wide variety and tremendous value of the rapidly growing collection within. More than 5,000 objects of art from the earliest civilization of Asia Minor to contemporary twentieth century art are exhibited. A distinctive feature is the installation of original old panelings with complete furnishings of the period. These include an English Georgian drawing room, a French Regence Salon, a Spanish-Italian room and an American

KANSAS CITY'S LIBERTY MEMORIAL

THE LIBERTY MEMORIAL

NIGHT VIEW

wing of five interiors brought from various sections of the Atlantic coast

The department of paintings already ranks fifth among museums of the United States and includes works by Titian Tintoretto Veronese, Rembrandt Rubens Hals, El Greco, Velasquez, Goya Poussin Chardin, Boucher Greuze Millet, Gainsborough, Reynolds, Raeburn, Copley, West Stuart and Inness

The classical collection contains sculpture, bronze and pottery from Egypt, Greece and Rome and the Egyptian Hawk, Greek Lion and Statue of Roman Patrician are almost unique in America The department of the Near and Far East contains treasures from Persia India China and Japan that cannot be duplicated in the United States

#### INDUSTRIAL KANSAS CITY

All of this, however, is but a tribute to the enterprise of the industrialist Though nineteenth in size Kansas City ranks first as a primary winter wheat market, in the distribution of kafir corn and milo maize grain sorghum seeds and as a market for hay stocker and feeder cattle and cash grain Kansas City's stockyards and meat-packing industry are second only to those of Chicago Its importance as a manufacturing center is widely recognized, offering more than 875 establishments First in the manufacture of poultry stock and dairy feeds in

the distribution of agricultural implements and the manufacture of American black walnut this volume of agricultural business places Kansas City seventh in amount of bank clearings and eleventh in value of manufactured products

Downtown Kansas City with its new Jackson County Court House Post Office Power and Light Building broadcasting stations and famous 'Peticoat Lane' bespeak its commercial importance

The Power and Light Building with its television laboratories broadcasting station and lighting bureau containing all manner of devices for testing sight should prove of particular interest to the medical profession

If time will permit without neglecting the numerous opportunities for exploring the city itself a number of interesting side trips can be suggested These include Lawrence Kan home of the University of Kansas Spooner Thayer Museum and Haskell Institute and federal training school for Indians a distance of forty miles, Fort Leavenworth regular army post of Indian border and Civil War importance and home of the federal penitentiary national soldiers home and federal disciplinary barracks and Shawnee Indian Mission a pioneer educational institution established in 1830

An abundance of fish and game make the resort centers in the Ozark country irresistible to the sportsman

## TRANSPORTATION

### Railroad Rates to Kansas City

Special rates have been granted for the benefit of members of the American Medical Association and dependent members of their families who will attend the annual session at Kansas City

The Central the New England, the Southeastern the Southwestern the Transcontinental the Trunk Line and the Western Passenger Associations, as well as the Eastern Line of the Canadian Passenger Association have granted a rate of one and one-third fares

To have the benefit of a return rate of one third fare it will be necessary for each member to secure a CERTIFICATE from the railroad ticket agent when he purchases his ticket to Kansas City The certificate must be certified to by the Secretary of the American Medical Association which may be done at the Registration Bureau to be located in the Kansas City Municipal Auditorium and must then be validated by a

Passenger Association and in the territories of the Central Passenger Association the Southeastern Passenger Association and the Trunk Line Association, from Arkansas Kansas Louisiana and Missouri as well as Natchez Miss and

FLYING TO KANSAS CITY

THE KANSAS CITY UNION STATION

representative of the railroads When the certificate is so certified and validated it will entitle its holder to purchase a return ticket to his home over the same route traveled to Kansas City, at one third fare

If the ticket agent at the member's home station does not have the certificate he will furnish information as to where and how it may be obtained

The certificate is not a receipt for money paid for a ticket nor will a receipt entitle its holder to secure a return trip ticket at a reduced rate Be sure to ask the ticket agent for a CERTIFICATE

The dates of sale of tickets to Kansas City will be May 7 to 13 in the territory of the Eastern Lines of the Canadian

Memphis Tenn in the territory of the Southwestern Passenger Association and from Illinois Iowa Kansas Manitoba Minnesota Missouri Nebraska northern Michigan North Dakota South Dakota and Wisconsin as well as Julesburg, Colo in the territories of the Transcontinental and Western Passenger Association

The dates of sale of tickets in the territory of the New England Passenger Association will be May 6 to 12 In the territories of the Southwestern Transcontinental and Western Passenger Associations the dates of sale of tickets from Colorado (except Julesburg) New Mexico (east of and including El Paso and Albuquerque) Oklahoma Texas and Wyoming will be May 6 to 12 and from Arizona British Columbia, California Idaho Montana Nevada New Mexico (west of Albuquerque and El Paso), Oregon Utah and Washington May 5 to 12

Certificates properly certified and validated will be honored for purchasing tickets for the return journey at one-third fare up to and including May 19 No refund of fare will be made on account of failure to present validated certificate when purchasing return ticket The return ticket must be used over the same route as that traveled going to Kansas City

When you purchase your ticket to Kansas City secure from the railroad ticket agent a CERTIFICATE which, when properly certified to and validated will entitle you to purchase a return ticket to your home over the same route traveled to Kansas City at one-third the fare paid to Kansas City

BE SURE TO ASK YOUR RAILROAD TICKET AGENT FOR A CERTIFICATE WHEN PURCHASING YOUR TICKET TO KANSAS CITY

Special Trains

The Burlington Railroad on the nights of May 10 and 11 will operate special modern Pullmans from Chicago to Kansas City for members of the American Medical Association their families and friends

The "American Royal" one of the Burlington's finest trains leaves the Union Depot Chicago at 7 p m and arrives at

Kansas City at 8 50 a m, Central Standard Time For reservations please communicate with Mr S J Owens, Burlington Railroad, 179 West Jackson Boulevard Chicago

Air Travel

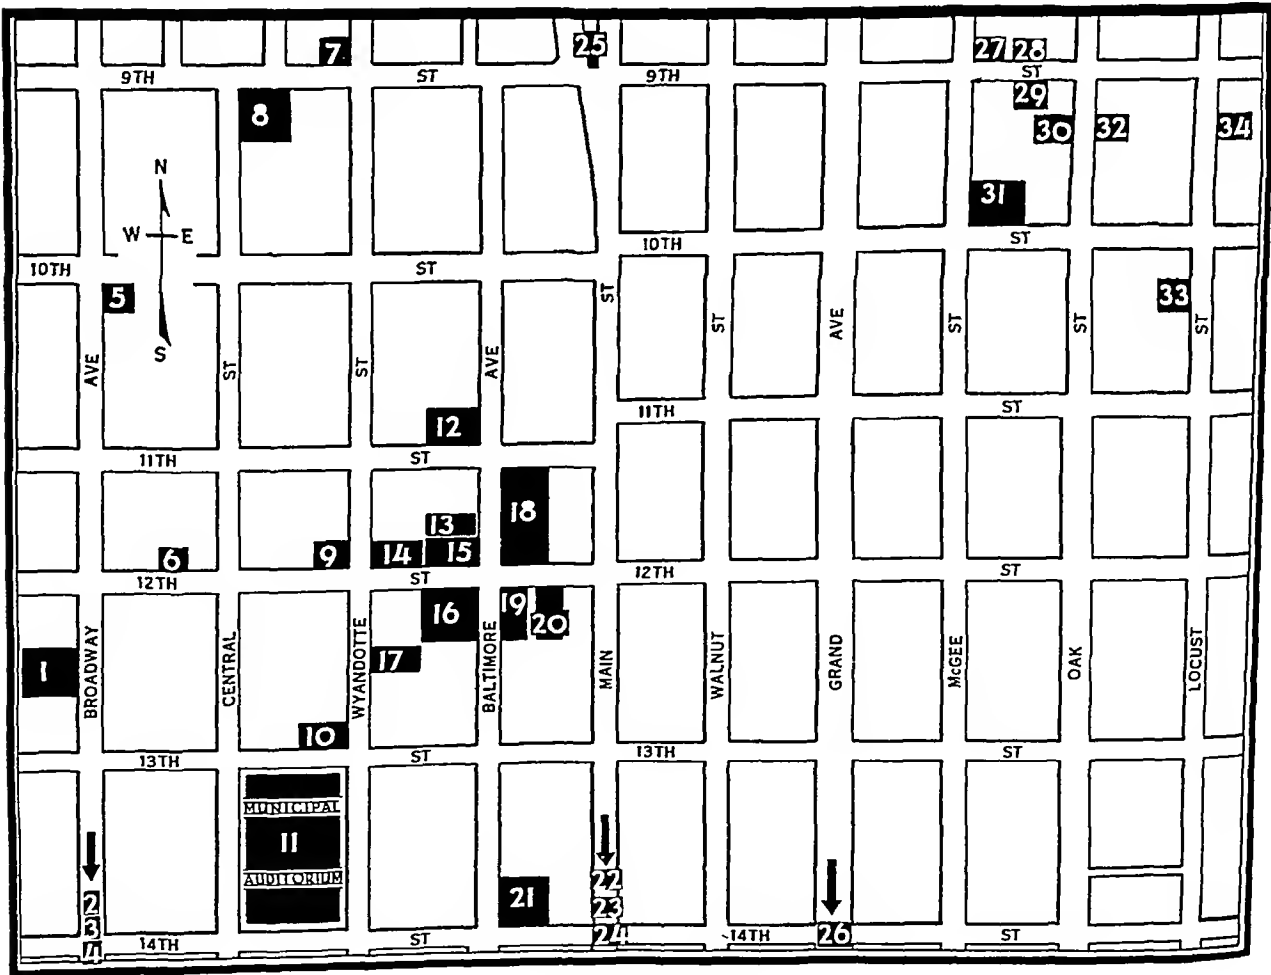

The Transcontinental and Western Air Inc announces air service to Kansas City in fourteen-passenger Douglas skyliners each containing a crew of three This service may be secured from Philadelphia, Pittsburgh Indianapolis St Louis and Columbus Ohio, as well as from Los Angeles Albuquerque N M Amarillo, Texas and Wichita Kan Passengers from New England may make connections at New York passengers from Michigan and Ohio at Chicago Local representatives may be consulted concerning discounts and savings in the use of script Meals will be served complimentary

REGISTRATION

The Bureau of Registration will be located in the Kansas City Municipal Auditorium, Fourteenth Street between Wyandotte and Central streets Members of the Subcommittee on Registration of the Local Committee on Arrangements will be

on hand to assist those who desire to register A branch post office in charge of government postoffice officials will be available for visitors and an information bureau will be operated in connection with the Bureau of Registration

### Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have on the prescribed form applied for Fellowship subscribed to THE JOURNAL and paid their Fellowship dues for the current year. The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues and these cards should be presented at the registration window. Any who have not received cards for 1936 should secure them at once by writing to the American Medical Association 535 North Dearborn Street Chicago.

### Members in Good Standing Eligible to Fellowship in the Association

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order that pocket cards may be secured and brought to Kansas City so that registration can be more easily and more promptly effected.

Application forms may be had on request.

Those subscribers to THE JOURNAL who have not received pocket cards for 1936 should write to the American Medical Association for application blanks and information as to further requirements.

### Register Early

Fellows living in Kansas City as well as all other Fellows who are in Kansas City on Monday and Tuesday should register as early as possible. The names of those who register will appear in the issue of the *Daily Bulletin* appearing the next day, and this will enable visiting physicians to find friends if they have registered.

### Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card which will be found on the tables in front of the Registration Bureau.

Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card and sign the application on the back. These cards will be found on the tables.

Entries on the registration cards should be written plainly or printed, as the cards are given to the printer to use as copy for the *Daily Bulletin* published on Tuesday Wednesday Thursday and Friday of the week of the session.

Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card together with their pocket cards at one of the windows marked Registration by Pocket Card. There the clerk will compare the two cards stamp the pocket card and return it and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session.

As previously stated it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association 535 North Dearborn Street Chicago so that their Fellowship may be entered not later than April 20. Any applications that are received later than April 20 will be given prompt attention but the Fellowship pocket card may not reach the applicant in time for him to register at the Kansas City session.

It will be possible for members of the organization to qualify as Fellows at Kansas City. In order to do this applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. It is suggested that those members who apply for Fellowship at Kansas City bring with them their state membership cards for 1936. The state membership card should be presented along with the filled in *blue* registration card at the window in the booth marked Applicants for Fellowship and Invited Guests.

As already stated registration can be effected more easily and more promptly if members will qualify as Fellows before leaving home.

### Registration for General Officers and Delegates at the Hotel Muehlebach

General Officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly at a booth near the Ballroom of the Hotel Muehlebach. This arrangement is made for the convenience of the members of the House of Delegates which will convene on Monday morning at 10 o'clock in the Ballroom of the Hotel Muehlebach. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock Monday morning May 11, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

### KANSAS CITY HOTELS

A list of Kansas City hotels is presented for the benefit of those who expect to attend the annual session of the American Medical Association May 11-15. Dr. Ira H. Lockwood is chairman of the Subcommittee on Hotels of the Local Committee on Arrangements and may be addressed at 102b Baltimore Avenue Kansas City Mo. The advertising announcement and coupon for reservations appear on advertising page 99 of this issue.

## GOLF TOURNAMENT

The American Medical Golfing Association will hold its twenty-second annual tournament at the Mission Hills and the Kansas City Country Clubs in Kansas City on Monday May 11.

Thirty-six holes of golf will be played in competition for the seventy trophies and prizes in the nine events. Trophies will be awarded for the Association Championship thirty-six holes gross the Will Walter Trophy the Association Handicap Championship thirty-six holes net, the Detroit Trophy the Championship Flight First Gross thirty-six holes the St. Louis Trophy the Championship Flight First Net thirty-six holes the President's Trophy the Eighteen Hole Championship the Golden State Trophy the Eighteen Hole Handicap

Championship the Ben Thomas Trophy the Maturity Event, limited to Fellows over 60 years of age the Minneapolis Trophy the Oldguard Championship limited to competition of past presidents the Wendell Phillips Trophy, and the Kickers Handicap the Wisconsin Trophy. Other events and prizes will be announced at the first tee.

### MEMBERS IN EVERY STATE OF THE UNION

M M Cullom of Nashville Tenn is president and W Albert Cook of Tulsa Okla and Walt P Conaway of Atlantic City N J are vice presidents of the American Medical Golfing Association which was organized in 1915 by Will Walter.

Wendell Phillips and Gene Lewis, and now totals 1150 members, representing every state in the Union. The living past presidents include Thomas Hubbard of Toledo Ohio, Fred Bailey of St Louis, Edward Martin of Media Pa, Robert Moss of LaGrange Texas, Charlton Wallace of New York, Will Walter of Chicago and Charlottesville Va, James Eaves of Oakland Calif, D Chester Brown of Danbury, Conn, Samuel Childs of Denver, W D Shelden of Rochester, Minn, Walter Schaller of San Francisco, Edwin Zabriskie of New York, Frial A Kelly of Detroit, John Welsh Crosley of Philadelphia, Homer K Nicoll of Chicago and Charles Lulens of Toledo.

#### KANSAS CITY COMMITTEE

The Kansas City Committee is under the general chairmanship of Clarence Capell, Rialto Building Kansas City Mo. He will be assisted by E R Deweese Vice Chairman and L G Allen J Wallace Beil C D Cantrell, Logan Clendenning, C C Dennie, Hugh A Gestring, A C Griffith John S Knight, T A Kyner A W McAlester Jr, Virgil W McCarty, C R McCubbin C A McGuire C J Mullen Paul J OConnell, A J Rettenmaier, H M Roberts E Kip Robinson C E Sanders, J S Snider, Albert S Welch and D A Williams.

#### TWO COURSES

To accommodate comfortably the large entry that is anticipated, the Kansas City Committee has arranged play over two very fine courses which touch corners the Mission Hills Country Club and the Kansas City Country Club. Their club houses are only one mile apart and ample transportation between the two has been arranged. Dinner for all players will be served in the Mission Hills Club House.

#### APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A M

G A. Write the executive secretary Bill Burns 2020 Olds Tower, Lansing Mich, for an application blank. Participants in the A M G A tournament are required to furnish their home club handicap signed by the secretary. No handicap over 30 is allowed except in the Kickers (Blind Bogey). Only active members of the A M G A may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

The twenty-second tournament of the American Medical Golfing Association promises to be a happy affair. The officers anticipate that some two hundred medical golfers from all parts of the United States will play.

#### SKEET AND TRAP SHOOT

The American Medical Skeet and Trap Shooters Association has been formed by a group of Kansas City physicians and it is hoped that the organization will be permanent. On the afternoon of May 10 there will be a Skeet and Trap Shoot at Elliott Gun Park.

Trap shoot—fifty sixteen yard targets

Class A, 94 per cent

Class B, 89 per cent

Class C, 84 per cent

Skeet shoot—fifty targets

### THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order that will be followed in the Official Program nor is the list complete. The Official Program will be similar to the pro-

grams issued in previous years and will contain the final program of each section with abstracts of the papers, as well as lists of committees, program of the Opening General Meeting, list of entertainments, map of Kansas City and other information. To prevent misunderstandings and protect the interest of advertisers it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

ARCHIBALD L HOYNE, Chicago

## SECTION ON PHARMACOLOGY AND THERAPEUTICS

MEETS IN OUTSIDE COMMITTEE ROOM, WANDOTTE STREET SIDE  
FOURTH FLOOR, MUNICIPAL AUDITORIUM

### OFFICERS OF SECTION

Chairman—CHAUNCEY D LEAKE, San Francisco  
Vice Chairman—N C GILBERT, Chicago  
Secretary—RUSSELL L HADEN, Cleveland  
Executive Committee—JOHN H MUSSEY, New Orleans CARL  
H GREENE, New York, CHAUNCEY D LEAKE, San Francisco

Wednesday, May 13—9 a m

Studies on the Optimal Dosage of Estrogenic Substances (Lan-  
tern Demonstration) CHARLES MAZER, Philadelphia  
Discussion to be opened by J P PRATT, Detroit

An Extract of the Adrenal Cortex Effective in Addison's Dis-  
ease (Lantern Demonstration)

WILLARD O THOMPSON, Chicago  
Discussion to be opened by RUSSELL M WILDER, Roches-  
ter, Minn

The Role of the Thymus and Pineal Gland in Growth and  
Development

LEONARD G ROWANTREE and N H EINHORN, Philadel-  
phia, and A M HANSON, Faribault, Minn

Chairman's Address The Practical Pharmacology of Central  
Nervous System Depressant Drugs

CHAUNCEY D LEAKE, San Francisco  
Experimental and Clinical Observations Regarding Angina Pec-  
toris and Some Related Symptoms (Lantern Demon-  
stration)

D E JACKSON and HELEN L JACKSON, Cincinnati  
Further Studies on the Mechanism of Action and the Relative  
Effectiveness of the Newer Diuretics (Lantern Demon-  
stration)

GEORGE R HERRMAN and GEORGE M DECHERD JR, Gal-  
veston, Texas

Discussion to be opened by JOSEPH M HAYMAN JR,  
Cleveland

Thursday, May 14—9 a m

JOINT MEETING WITH SECTION ON PRACTICE OF MEDICINE NORTH  
HALF OF ARFAA, MUNICIPAL AUDITORIUM

The Clinical Use and Dangers of Hypnotics (Lantern Demon-  
stration) SOFIA WRISS, Boston

Address WILLIAM J KERR, San Francisco  
The Clinical Use of Diuretics (Lantern Demonstration)

JOSEPH M HAYMAN JR, Cleveland  
Clinical Evaluation of Fever Therapy (Motion Picture Demon-  
stration) STAFFORD L WARREN, Rochester, N Y

Notes on Treatment of Histolytic Infection in Man (Lantern  
Demonstration) W M JAMES, Panama, C Z

Friday, May 15—9 a m

Election of Officers

Cinchophen—Is There a Safe Method of Administration (Lan-  
tern Demonstration)?

WALTER L PALMER and PAUL S WOODALL, Chicago  
Discussion to be opened by MANFRED W COMFORT, Roches-  
ter, Minn

Individualizing Time of Administration of Insulin Use of  
Postprandial Insulin MILTON PLOTZ, Brooklyn  
Discussion to be opened by RALPH H MAJOR, Kansas  
City, Mo

Results of Dietary and Medical Treatment in Disease of the  
Gallbladder (Lantern Demonstration)

J R TWISS and C H GREFF, New York  
Discussion to be opened by GEORGE B EUSTEFMAN,  
Rochester, Minn, EVARTS A GRAHAM, St Louis, and  
J M BLACKFORD, Seattle

The Present Status of Research and Teaching in Pharmacology  
NORMAN A DAVID, Cincinnati, and GEORGE A EMERSON,  
Morgantown, W Va

Discussion to be opened by H B HAUG, Richmond, Va  
and O W BARLOW, Cleveland

Hypersensitiveness to Cold with Local and Systemic Manifest-  
ations of a Histamine like Character Its Amenable-  
ness to Treatment (Lantern Demonstration)

BAIRD T HORTON, Rochester, Minn  
Discussion to be opened by W W DUKE, Kansas City,  
Mo

A Pharmacologic Study of the Toxemia Theory of Surgical  
Shock (Lantern Demonstration)

CARL A DRAGSTEDT, Chicago

Discussion to be opened by ALFRED BLALOCK, Nashville,  
Tenn, and D B PHENISTER, Chicago

## SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS IN OUTSIDE COMMITTEE ROOM, WANDOTTE STREET SIDE,  
FOURTH FLOOR, MUNICIPAL AUDITORIUM

### OFFICERS OF SECTION

Chairman—HENRY C SWEANY, Chicago  
Vice Chairman—W E GARREY, Nashville, Tenn  
Secretary—J J MOORE, Chicago  
Executive Committee—WILLIAM CARPENTER MACCARTY, Roch-  
ester, Minn, ELIAS P LYON, Minneapolis, HENRY C  
SWEANY, Chicago

Wednesday, May 13—2 p m

Chairman's Address Pathologic Interpretation of Roentgeno-  
logic Shadows of Pneumococcosis (Lantern Demon-  
stration) HENRY C SWEANY, Chicago

Laboratory Diagnosis of Infectious Mononucleosis (Lantern  
Demonstration) ISRAEL DAVIDSON, Chicago

Discussion to be opened by RICHARD H JAFFE, Chicago,  
and A S GIORDANO, South Bend, Ind

Chronic Thyroiditis (Lantern Demonstration)

RICHARD H JAFFE, Chicago

End Results of Very Radical Thyroidectomies (Lantern Dem-  
onstration) ARTHUR E HERTZLER, Halstead, Kan

Nervous System and Internal Secretions

LEON ASHER, Bern, Switzerland

Specific Artificial Immunity in Tuberculosis (Lantern Dem-  
onstration)

HARRY J CORPER, MAURICE L COHN, and A P DAME-  
ROW, Denver

Surgical Shock in Peritonitis Due to Bile and to Liver Autol-  
ysis (Lantern Demonstration)

HENRY N HARKINS, Chicago

Discussion to be opened by LESTER R DRAGSTEDT and  
EDMUND ANDREWS, Chicago, and THOMAS G ORR,  
Kansas City, Mo

The Blood Nitrite EDWARD J STIEGLITZ, Chicago  
Discussion to be opened by ANTON J CARLSON, Chicago

Thursday, May 14—2 p m

### SIMPOSIUM ON VITAMINS

Historical Aspects of the Vitamins

E V MCCOLLUM, Baltimore

The Chemistry of Vitamins (Lantern Demonstration)

C G KING, Pittsburgh

Chemistry of Vitamin A (Lantern Demonstration)

H A MATTHEW, Iowa City

Chemistry of the Vitamin B Complex (Lantern Demonstra-  
tion) RICHARD J BLOCK, New York

New Forms and Sources of Vitamin D (Lantern Demonstra-  
tion) CHARLES E BILLS, Evansville, Ind

The Pathologic Changes Resulting from Vitamin Deficiency  
(Lantern Demonstration) S B WOLBACH, Boston

Clinical Manifestations of Vitamin Deficiency (Lantern Dem-  
onstration) JOHN B YOUMANS, Nashville, Tenn

Physiology of Vitamins ANTON J CARLSON, Chicago

Friday, May 15—2 p m

Election of Officers  
Shwartzman Phenomena (Lantern Demonstration)

GRIGORY SHWARTZMAN, New York  
Discussion to be opened by PAUL KLEMPFNER and I L  
GFRBER, New York

The Clinical Diagnosis of Periarteritis Nodosa (Lantern Dem-  
onstration)

MILTON B COHEN, BENJAMIN S KLINE, and ANNA  
MAY YOUNG, Cleveland

Identification of the Cancer Cell (Lantern Demonstration)

WILLIAM CARPENTER MACCARTY, Rochester, Minn

The Effects of Intravenous Injections of Salt Solution in Col-  
lapse Due to Mechanical Impounding of Blood in the  
Splanchnic Region (Lantern Demonstration)

JAMES P SIMMONS, Chicago

Studies on the Relation of Micro Organisms to Allergy IV  
Seasonal Hay Fever and Asthma Due to Molds (Lantern  
Demonstration) SAMUEL M FARBBERG, Chicago

## Myocardial Syphilis (Lantern Demonstration)

JACK C NORRIS, Atlanta, Ga  
Discussion to be opened by CARL V WELLER, Ann Arbor, Mich, and REGINALD FITZ, Boston

## The Physiologic Effects of Fever Therapy as Related to the Preparation and Various Sedatives Employed

ANDREW H DOWDY and FRANK W HARTMAN, Detroit  
Discussion to be opened by WALTER M SIMPSON, Dayton, Ohio

## SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN ASSEMBLY ROOM SIXTH FLOOR,  
MUNICIPAL AUDITORIUM

## OFFICERS OF SECTION

Chairman—HANS H F REESE, Madison Wis  
Vice Chairman—PERCIVAL BAILEY, Chicago  
Secretary—HENRY R VITTS, Boston  
Executive Committee—HENRY W WOLTMAN Rochester, Minn,  
H DOUGLAS SINGER, Chicago, HANS H F REESE, Madison, Wis

Wednesday, May 13—9 a m

## Epidermoid Tumors of the Brain (Lantern Demonstration)

J GRAFTON LOVE Rochester, Minn  
Discussion to be opened by ERNEST SACHS, St Louis, and R GLEN SPURLING, Louisville Ky

## Encephalography with Ethylene (Lantern Demonstration)

HENRY W NEWMAN San Francisco  
Discussion to be opened by JOHN J KEEGAN, Omaha  
Neoplasms of the Spinal Cord Report of a Series of Forty-Two Surgical Cases (Lantern Demonstration)  
R GLEN SPURLING and FRANK H MAYFIELD, Louisville, Ky

Discussion to be opened by PERCIVAL BAILEY, Chicago, and FRANK R TEACHENOR, Kansas City, Mo

## Newer Aspects of Meniere's Disease Diagnosis and Treatment (Lantern Demonstration)

WALTER E DANDY, Baltimore  
Discussion to be opened by FRANK R TEACHENOR, Kansas City Mo, and FRANCIS C GRANT, Philadelphia

## Alcohol Injection in the Treatment of Major Trigeminal Neuralgia (Lantern Demonstration)

FRANCIS C GRANT, Philadelphia  
Discussion to be opened by WALTER E DANDY, Baltimore, and J GRAITON LOVE, Rochester Minn

## The Treatment of Encapsulated Brain Abscess A Method Whereby the Wall Is Brought To or Above the Surface Preliminary to Drainage (Lantern Demonstration)

EDGAR A KAHN Ann Arbor, Mich  
Discussion to be opened by R GLEN SPURLING, Louisville, Ky, and JOSEPH E J KING, New York

Thursday, May 14—9 a m

## SYMPOSIUM ON THE ACTION POTENTIALS OF THE BRAIN

## I In Normal Persons and in Normal States of Cerebral Activity (Lantern Demonstration)

HALLOWELL DAVIS and PAULINE A DAVIS, Boston

## II In Certain Types of Mental Deficiency (Lantern Demonstration)

GEORGE KREEZER, Vineland N J

## III In Epilepsy (1) Significance for Diagnosis and Localization (2) Effect of Drugs and of Conditions Which Influence Seizures (Lantern Demonstration)

FRDERIC A GIBBS, WILLIAM G LENNON and ERNA L GIBBS, Boston

Discussion to be opened by L E TRAVIS, Iowa City

## Fever Therapy in Tabes Dorsalis The Relief of Gastric Crises and Lightning Pains by the Use of the Kettering Hypertherm

A E BENNETT Omaha  
Discussion to be opened by FRANKLIN G EBAUGH, Denver

## A Comparative Study of Artificial Hyperpyrexia and Therapeutic Malaria in the Treatment of Paresis A Preliminary Report (Lantern Demonstration)

CLARKE H BARNACLE, FRANKLIN G EBAUGH and JACK R EWALT, Denver

Discussion to be opened by A E BENNETT, Omaha

Friday, May 15—9 a m

## Election of Officers

## Chairman's Address The History of Scalping and Its Clinical Aspects (Lantern Demonstration)

HANS H F REESE, Madison Wis

## Psychoneurotic Depressions

CHARLES H KIMBERLY, Stockbridge, Mass  
A Children's Hospital for Neurologic and Behavior Disorders Five Years' Experience at the Emma Pendleton Bradley Home (Lantern Demonstration)

CHARLES BRADLEY, East Providence R I  
Discussion to be opened by WILLIAM G LENNON, Boston

## The Visceral Nervous System and Its Relation to the Endocrines

HOMER P RUSH Portland, Ore

## Unilateral Cerebral Dominance as Related to Mind Blindness The Minimal Lesion Capable of Causing Visual Agnosia for Objects

J M NIELSEN, Los Angeles  
Discussion to be opened by JOHN B DOYLE, Los Angeles, and GEORGE B HASSIN, Chicago

## Toxic Focal Lesions in the Central Nervous System (Lantern Demonstration)

LOUIS L TURLEN, SIDNEY I SCHWAB and JOSEPH J GITT, St Louis

Discussion to be opened by ROY R GRINKER and GEORGE B HASSIN, Chicago

## SECTION ON DERMATOLOGY AND SYPHILOLOGY

MEETS IN INSIDE COMMITTEE ROOM, FOURTH FLOOR,  
MUNICIPAL AUDITORIUM

## OFFICERS OF SECTION

Chairman—HARRY R FOERSTER, Milwaukee  
Vice Chairman—JOHN G DOWNING, Boston  
Secretary—J BEDFORD SHELMIERE, Dallas, Texas  
Executive Committee—C GUY LANE, Boston, JEFFREY C MICHAEL, Houston, Texas, HARRY R FOERSTER, Milwaukee

Wednesday, May 13—9 a m

## Chairman's Address Some Observations on Industrial Dermatology

HARRY R FOERSTER, Milwaukee

## Lupus Erythematosus A Modification of Therapy with Gold Compounds

HFRBERT S ALDEN and JACK W JONES Atlanta, Ga  
Discussion to be opened by JAMES K HOWLRS, New Orleans

## Histopathology of Various Types of Cutaneous Tuberculosis (Lantern Demonstration)

HAMILTON MONTGOMERY, Rochester, Minn  
Discussion to be opened by DUNCAN O POTH, San Antonio, Texas

## Besnier-Boeck's Disease (Lantern Demonstration)

JAMES W JORDON and EARL D OSBORNE, Buffalo  
Discussion to be opened by J P GULQUIERRE, Philadelphia

## Lichen Ruber Moniliformis Report of a Hitherto Undescribed Variety of a Rare Dermatoses (Lantern Demonstration)

FRED WISE, CHARLES R REIN and DAVID L SATENSTEIN, New York

Discussion to be opened by F M JACOB, Pittsburgh

## Aleukemic Reticulosis An Additional Member of the So Called Cutaneous Lymphoblastomas (Lantern Demonstration)

JAMES T WAYSON Honolulu, H I, and FRED D WEIDMAN, Philadelphia

## Cutaneous Lesions Associated with Monocytic Leukemia and Reticulo-Endotheliosis (Lantern Demonstration)

FRANCIS W LYNCH, St Paul  
Discussion on papers of DRS WAYSON and WEIDMAN and DR LYNCH to be opened by A B LOVENAN, Louisville Ky

Thursday, May 14—9 a m

## The Treatment of Lip Cancer A Clinical Survey of Four Hundred Cases Treated by Different Methods (Lantern Demonstration)

EUGENE A HAND and UDO J WILE, Ann Arbor Mich  
Discussion to be opened by EVERETT S LAIN, Oklahoma City

## Some Patch Test Observations Based on Five Years' Experience in More Than Nine Hundred Patients with More Than Ten Thousand Tests (Lantern Demonstration)

ADOLPH ROSTENBERG JR and MARION B SULZBERGER, New York

Discussion to be opened by M E OBERMAYER Chicago

The Relation of Diet to Skin Infection A Study of the Influence of High and Low Carbohydrate and High Fat Intakes and Starvation on Experimental Pyogenic Skin Infections in Dogs (Lantern Demonstration)  
DONALD M PILLSBURY and THOMAS H STERNBERG, Philadelphia

Discussion to be opened by JOHN F MADSEN, St Paul  
"Fixed" Drug Eruptions

E WILLIAM ADAMOWITZ, New York, and MAURICE H NOON, Des Moines Iowa

Discussion to be opened by MARQUE O NELSON, Tulsa, Okla

Extracellular Cholesterinosis (Lantern Demonstration)  
CARL W LAYMON, Minneapolis

Discussion to be opened by C GUY LANE Boston  
Streptococcic Dermatoses of the Ears (Lantern Demonstration)

JAMES HERBERT MITCHELL Chicago  
Discussion to be opened by CLINTON W LANE, St Louis

Vitamin C and Pigment (Lantern Demonstration)  
THEODORE CORNBLEET, Chicago

Discussion to be opened by S W BRCKER Chicago  
Friday, May 15—9 a m

Election of Officers  
Resistant Early Syphilis in Two Instances of Conjugal Infection (Lantern Demonstration)

C W NETHERTON Cleveland  
Discussion to be opened by JOHN ERIC DALTON, Indianapolis

Ulcerative Lesions of the Skin in Lymphogranuloma Inguinale (Lantern Demonstration)

MAX S WIEN and MINNIE ODOLER PERLSTEIN Chicago  
Untreated Syphilis in the Male Negro A Comparative Study of Treated and Untreated Cases (Lantern Demonstration)

R A VONDERLEHR Washington D C  
Discussion to be opened by CHARLES C DENNIE, Kansas City Mo

A Study of the Rapidity with Which Spirochaeta Pallida Invades the Blood Stream (Lantern Demonstration)

GEORGE W RAIZISS and MARIE SEVERAC, Philadelphia  
Discussion to be opened by RICHARD L SUTTON JR, Kansas City, Mo

Cod Liver Oil Ointments in the Treatment of Indolent Ulcers (Lantern Demonstration)

J R DRIVER, GEORGE W BINKLEY and MAURICE SULLIVAN, Cleveland  
Discussion to be opened by EVERETT C FOX, Dallas, Texas

Clinical Evaluation of a New Trichophyton Extract "Dermatomycol"  
J J ELLER and K A KAZANJIAN New York

Discussion to be opened by HARRY P JACOBSON, Los Angeles

## SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

MEETS IN CONGRESS ROOM HOTEL PRESIDENT

### OFFICERS OF SECTION

Chairman—R R SAYERS, Washington, D C  
Vice Chairman—J LYNN MAHAFFEY Camden N J

Acting Secretary—IRL C RIGGIN Richmond Va  
Executive Committee—WILSON G SWILLIE Boston ROBERT H RILEY, Baltimore, R R SAYERS Washington D C

Wednesday, May 13—2 p m

### INDUSTRIAL MEDICINE

Chairman's Address Industrial Hygiene Problems in the United States (Lantern Demonstration)

R R SAYERS Washington D C  
Papilloma and Carcinoma of the Urinary Bladder in Dye Workers (Lantern Demonstration)

GEORGE H GEHRMANN Wilmington, Del  
Anthracosilicosis (Lantern Demonstration)

W C DRESSEY and R R JONES Washington D C  
Safe Practices in the Industrial Use of Carbon Tetrachloride

HENRY FIELD SMITH Philadelphia  
A New Procedure for the Control of Benzene Poisoning

H H SCHRECK and W P YANT, Pittsburgh  
Thursday May 14—2 p m

### PREVENTIVE MEDICINE

Poliomyelitis, Present Knowledge and Its Bearing on Control (Lantern Demonstration)

J P LEAKE Washington D C

Immediate Treatment and After-Care of Poliomyelitis Patients (Lantern Demonstration)

THEODORE C HEMPELMANN, St Louis  
Rabies and What to Do for the Person Bitten

V H BASSETT, Savannah Ga  
The Opsonocytaphagic Allergic and Agglutination Reactions in the Diagnosis of Undulant Fever (Lantern Demonstration)

A E KELLER, CRIT PHARRIS and W H GAUB, Nashville Tenn

Significance of an Epidemic of Dengue  
T H D GRIFFITHS and HENRY HANSON, Jacksonville Fla

The Evaluation of the Ragweed Hay Fever Resort Areas of North America (Lantern Demonstration)

O C DURHAM, Chicago  
Friday, May 15—2 p m

### PUBLIC HEALTH

Election of Officers  
The Physician's Place in the Public Health Program

W W BAUER Chicago  
What Service Does a Health Department Render to the Practicing Physician?

JOSEPH F BREDECK St Louis  
The Functions of a State Health Department (Lantern Demonstration)

E G BROWN Topeka Kan  
Discussion to be opened by WALTER L BIFFRING, Des Moines, Iowa

Medical Aspects of Accident Control  
L D BRISTOL New York

Chronic Endemic Dental Fluorosis (Mottled Enamel) (Lantern Demonstration)

H T DEAN Washington, D C

## SECTION ON UROLOGY

MEETS IN INSIDE COMMITTEE ROOM FOURTH FLOOR, MUNICIPAL AUDITORIUM

### OFFICERS OF SECTION

Chairman—JOHN H MORRISSEY New York  
Vice Chairman—C H DE T SIVERS, Atlantic City, N J

Secretary—WILLIAM P HERDST JR, Washington, D C  
Executive Committee—HARRY CULVER Chicago, STANLEY R WOODRUFF, Jersey City, N J, JOHN H MORRISSEY, New York

Wednesday, May 13—2 p m

Injection Treatment for Hydrocele  
GEORGE H EWELL, Madison Wis

Transurethral Surgery Changing Conceptions During the Past Five Years (Lantern Demonstration)

GERSHON J THOMPSON Rochester, Minn  
Water Balance in Surgical Patients (Lantern Demonstration)

WALTER G MADDOCK, Ann Arbor, Mich  
Present Status of Dietary Regimens in Treatment of Urinary Calculi (Lantern Demonstration)

CHARLES C HIGGINS, Cleveland  
Present Status of Dietary Regimens in Urinary Infections

ANSON L CLARK Oklahoma City  
The Present Status of Cystometry (Lantern Demonstration)

D K ROSE St Louis  
Presentation of New Instrument for Electrosurgical Uretero-Intestinal Anastomosis

FREDERIC E B FOLEY, St Paul  
Thursday, May 14—2 p m

Chairman's Address  
JOHN H MORRISSEY, New York

The Value of Fever Therapy in the Treatment of Gonorrhea  
C A OWENS Omaha

Ureteropelvic Obstruction of the Noncalculous Type in Hydro-nephrosis (Lantern Demonstration)

T D MOORE, Memphis Tenn  
Results of Transurethral Prostatic Resection (Lantern Demonstration)

N G ALCOCK, Iowa City  
Recent Developments in Excretion Urography

MOSSES SWICK New York  
Intraprostatic Injection An Experimental Study by Vincent O Connor and Robert L Ladd (Lantern Demonstration)

VINCENT J O CONOR, Chicago  
Friday, May 15—2 p m

Election of Officers  
The Endocrines in Sterility

LEOPOLD LICHTWITZ New York  
The Gynecologic Aspect of Human Sterility

SAMUEL R MFAKEL Boston

Methods of Sperm Analysis, with the Valuation of Therapeutic Procedures (Lantern Demonstration)

ROBERT S. HOTCHKISS, New York

Inflammatory Occlusion of the Epididymis in Male Sterility (Lantern Demonstration)

FRANCIS R. HAGNER, Washington, D. C.

Granuloma Inguinale (Lantern Demonstration)

JESSE ULLMAN REAVES, Mobile, Ala.

Analysis of Indications for and Results of Cystoscopic Examination (Lantern Demonstration)

M. A. NICHOLSON, Duluth, Minn.

## SECTION ON ORTHOPEDIC SURGERY

MEETS IN ASSEMBLY ROOM SIXTH FLOOR,  
MUNICIPAL AUDITORIUM

### OFFICERS OF SECTION

Chairman—ARTHUR T. LEGG, Boston

Vice Chairman—FRYMONT A. CHANDLER, Chicago

Secretary—ROBERT V. FUNSTEN, University, Va.

Executive Committee—JAMES S. SPEED, Memphis, Tenn.; ROBERT D. SCHROCK, Omaha; ARTHUR T. LEGG, Boston

Wednesday, May 13—2 p. m.

Results Obtained by the Subcutaneous Fixation of Fractures of the Neck of the Femur (Lantern Demonstration)

J. ALBERT KEV, St. Louis

Discussion to be opened by ELLIS W. JONES, Los Angeles, Edwin W. RYERSON, Chicago, and FRED KNOWLES, Fort Dodge, Iowa

Fractures of the Neck of the Femur in Children (Lantern Demonstration)

JOSEPH I. MITCHELL, Memphis, Tenn.

Discussion to be opened by FRANK R. OBER, Boston; GUY W. LEADBETTER, Washington, D. C.; and ROBERT G. PACKARD, Denver

The Evaluation of the Various Methods of Treatment Advanced for Fractures of the Neck of the Femur

PAUL B. MAGNUSON, Chicago

Discussion to be opened by FREDERICK C. KIDNER, Detroit; CLAY RAY MURRAY, New York; and FRANK D. DICKSON, Kansas City, Mo.

A New Lateral Roentgenogram of the Femoral Neck (Lantern Demonstration)

ALBERT B. FERGUSON, New York

Discussion to be opened by FRED J. GAENSELEN, Milwaukee, and J. S. SPEED, Memphis, Tenn.

Chairman's Address (Lantern Demonstration)

ARTHUR T. LEGG, Boston

Massive Resection and Bone Graft Replacement in Sarcoma of the Long Bones (Motion Picture Demonstration)

FRED H. ALBEE, New York

Discussion to be opened by ARTHUR STEINDLER, Iowa City, and HENRY W. MEYERDING, Rochester, Minn.

Thursday, May 14—2 p. m.

The Treatment of Osteomyelitis, with a Report of Five Hundred Cases (Lantern Demonstration)

MARCUS H. HOBART, Evanston, Ill.

Discussion to be opened by R. J. DITTRICH, Fort Scott, Kan.; JACOB KULOWSKI, St. Joseph, Mo.; and J. E. M. THOMSON, Lincoln, Neb.

Osteomyelitis of the Ilium, Acute and Chronic (Lantern Demonstration)

CARL E. BADGLEY, Ann Arbor, Mich.

Discussion to be opened by WILLIS C. CAMPBELL, Memphis, Tenn.; and W. B. CARRELL, Dallas, Texas

Osteomyelitis of the Spine (Lantern Demonstration)

GUY A. CALDWELL, Shreveport, La.

Discussion to be opened by ABRAHAM O. WILENSKI, New York; and ALFRED R. SHANDS JR., Durham, N. C.

Acute Hematogenous Osteomyelitis: An Analysis of Seventy-Five Cases (Lantern Demonstration)

ROBERT C. ROBERTSON, Chattanooga, Tenn.

Discussion to be opened by ROBERT C. LONGERAN, Evanston, Ill.; and HERBERT A. DURHAM, Shreveport, La.

Growth Changes in Bone as a Result of Osteomyelitis in Children (Lantern Demonstration)

JOHN C. WILSON, Los Angeles

Discussion to be opened by D. B. PHEMISTER, Chicago, and J. D. BISGARD, Omaha

Late Infection Following the Use of Wire and Pins in Bone

SYLVAN L. HAAS, San Francisco

Discussion to be opened by LE ROI C. ABBOTT, San Francisco, and ROGER ANDERSON, Seattle

Friday, May 15—2 p. m.

### Election of Officers

Tuberculosis of the Hip in Children (Lantern Demonstration)

JOSEPH S. BARR, Boston

Discussion to be opened by ARTHUR STEINDLER, Iowa City

The Massive Bone Graft (Lantern Demonstration)

MELVIN S. HENDERSON, Rochester, Minn.

Discussion to be opened by OSCAR L. MILLER, Charlotte, N. C.; HERMAN C. SCHUMM, Milwaukee; and FRYMONT A. CHANDLER, Chicago

The Operative versus the Manipulative Treatment of Slipped Femoral Epiphysis, with a Description of a Curative Operation (Lantern Demonstration)

SAMUEL KLEINBERG and JOSEPH BUCHMAN, New York

Discussion to be opened by ARMITAGE WHITMAN, New York; CHARLES W. PEABODY, Detroit; and W. EUGENE WOLCOTT, Des Moines, Iowa

The Physiologic Effects of the Correction of Faulty Posture (Lantern Demonstration)

LOUIS B. LAIDLAC and JESSE T. NICHOLSON, Philadelphia

Discussion to be opened by LLOYD T. BROWN, Boston; and WILLIAM BATES and DORFST P. WILLARD, Philadelphia

A Conservative Treatment of Habitual Dislocations of the Shoulder (Lantern Demonstration)

ARTHUR G. DAVIS, Erie, Pa.

Discussion to be opened by JAMES WARREN SEYER, Boston; ENSON B. FOWLER, Evanston, Ill.; and DAVID M. BOSWORTH, New York

Chronic Scleritis Due to Adhesions About the Nerve Trunk and the Results of Their Removal by Operation

GEORGE WAGONER, Haverford, Pa.

Discussion to be opened by ALBERT H. FREIBERG, Cincinnati; ARCHIBALD F. O'DONOGHUE, Sioux City, Iowa; and ROBERT M. SCHAUFFERT, Kansas City, Mo.

## SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN CONGRESS ROOM, HOTEL PRESIDENT

### OFFICERS OF SECTION

Chairman—ERNEST H. GAITHER, Baltimore

Vice Chairman—LOUIS A. BUIE, Rochester, Minn.

Secretary—A. H. AARON, Buffalo

Executive Committee—ALBERT F. R. ANDRESEN, Brooklyn; WALTER A. FANSLER, Minneapolis; ERNEST H. GAITHER, Baltimore

Wednesday, May 13—9 a. m.

Multiple Polypsis of Colon, Familial Factor and Malignant Tendency (Lantern Demonstration)

D. C. MCKENNEY, Buffalo

Discussion to be opened by T. E. JONES, Cleveland, and J. J. CORBETT, Detroit

Disseminated Polypsis of the Colon (Lantern Demonstration)

CHARLES W. MAYO and E. G. WAKEFIELD, Rochester, Minn.

Discussion to be opened by FRANK H. LAHEY, Boston; and WALTER A. FANSLER, Minneapolis

Clinical Significance of Indicanuria (Lantern Demonstration)

H. W. SOPER, St. Louis

Discussion to be opened by A. L. LEVIN, New Orleans

The Relation of Gastro-Enterology to General Medicine

NELSON G. RUSSELL, Buffalo

Discussion to be opened by GEORGE B. EUSTERMANN, Rochester, Minn.

Alcohol and Cirrhosis of the Liver: Clinical and Pathologic Considerations (Lantern Demonstration)

RUSSELL S. BOLES and JEFFERSON H. CLARK, Philadelphia

Discussion to be opened by HARRY L. BOCKUS and LEONARD G. ROWNTREE, Philadelphia

The Relationship of the Serum Phosphatase Value in the Blood in the Differential Diagnosis of Obstructive and Hepato-

cellular Jaundice (Lantern Demonstration)

DAVID R. MERANZE and MAURICE M. ROTHMAN, Philadelphia

Discussion to be opened by LEONARD G. ROWNTREE, Philadelphia, and J. RUSSELL TWISS, New York

Serum Proteins in Hepatic Diseases (Lantern Demonstration)  
HARRY L BOCKUS and H J TUMEN, Philadelphia  
Discussion to be opened by A M SNELL, Rochester, Minn

Thursday, May 14—9 a m

Chairman's Address Recent Advances in Gastro-Enterology  
ERNEST H GAITHER, Baltimore

Chronic Gastritis (Lantern Demonstration)  
RUDOLF SCHINDLER, MARIE ORTMAYER and JOHN F RENSCHAW, Chicago

Discussion to be opened by WILLIAM C MACCARTY, Rochester, Minn, CHESTER M JONES, Boston, and LEON BLOCH, Chicago

The Leukopenic Index as a Diagnostic Method in the Study of Food Allergy (Lantern Demonstration)

WARREN T VAUGHAN, Richmond Va  
Discussion to be opened by W W DUKE, Kansas City, Mo, L P GAY, St Louis and HERBERT J RINKEL, Kansas City, Mo

The Etiology of Pruritus Ani Clinical and Histologic Manifestations in Forty-Three Cases (Lantern Demonstration)  
C C TUCKER and C A HELLWIG, Wichita Kan  
Discussion to be opened by HARRY E BACON, Philadelphia

The Surgical Treatment of Pruritus Ani (Lantern Demonstration)  
MAPION C PRUITT, Atlanta, Ga  
Discussion to be opened by HARVEY B STONE, Baltimore

The Clinical Significance of Negative Roentgen Examinations in Patients with Chronic Dyspepsia (Lantern Demonstration)  
GEORGE B EUSTERMAN, Rochester, Minn  
Discussion to be opened by EDWARD H SKINNER, Kansas City, Mo, and NELSON G RUSSELL, Buffalo

Friday, May 15—9 a m

Election of Officers

The Importance of Routine Examination of the Colon (Lantern Demonstration)  
LOUIS J HIRSCHMAN, Detroit  
Discussion to be opened by W H KIGER, Los Angeles, and D C MCKENNEY, Buffalo

Diaphragmatic Hernia Symptomatology, Diagnosis and Treatment (Lantern Demonstration)  
SAMUEL MOREIN, Providence, R I

Discussion to be opened by P E TRUESDALE, Fall River, Mass, and I R JANKELSON, Boston

A Review of the Gastric Ulcer Problem (Lantern Demonstration)  
SARA M JORDAN, Boston  
Discussion to be opened by SIDNEY A PORTIS, Chicago, and RUSSELL S BOLES, Philadelphia

Treatment of Intractable Peptic Ulcer by Intramuscular Injections of Metallic Bismuth (Lantern Demonstration)  
FRANK D GORHAM, St Louis

Discussion to be opened by A F R ANDRESEN, Brooklyn

Comparative Value of Dietetic, Surgical and Parenteral Treatment in Peptic Ulcer (Lantern Demonstration)

DAVID J SANDWEISS, Detroit  
Discussion to be opened by SARA M JORDAN, Boston, and GEORGE B EUSTERMAN, Rochester, Minn

Carcinoma of the Rectum Factors Affecting Its Cure  
G V BRINDLEY, Temple, Texas

Discussion to be opened by CLYCE ROSSER, Dallas Texas and FRED W RANKIN, Lexington, Ky

Secondary Resections in Recurring Carcinoma of the Colon (Lantern Demonstration)  
J W THOMPSON, St Louis  
Discussion to be opened by C J HUNT, Kansas City, Mo, and C F DIXON, Rochester, Minn

## SECTION ON RADIOLOGY

MEETS IN INSIDE COMMITTEE ROOM, FIFTH FLOOR  
MUNICIPAL AUDITORIUM

### OFFICERS OF SECTION

Chairman—EDWARD L JENKINSON, Chicago

Vice Chairman—ROSS GOLDEN, New York

Secretary—JOHN T MURPHY, Toledo, Ohio

Executive Committee—A U DESJARDINS, Rochester, Minn  
JOHN W PIERSON, Baltimore, EDWARD L JENKINSON, Chicago

Wednesday, May 13—9 a m

Chairman's Address Cholecystography (Lantern Demonstration)  
EDWARD L JENKINSON, Chicago

Ulcer Crater Visualized by Pressure (Lantern Demonstration)  
HOLLIS E POTTER, Chicago

Cancer of the Duodenum A Clinical and Radiologic Study of Sixteen Cases (Lantern Demonstration)  
WILLIAM J HOFFMAN and GEORGE T PACK, New York

Some Observations on the Physiology and Pathology of the Small Intestine (Lantern Demonstration)  
E P PENDERGRASS, Philadelphia

Comparison of Methods of Roentgen Examinations of the Colon (Lantern Demonstration)  
JAMES T CASE, Chicago

Roentgenkymography Its Clinical and Physiologic Value in Diseases of the Heart and Chest (Lantern Demonstration)  
SHERWOOD MOORE and WENDELL G SCOTT, St Louis

Thursday, May 14—9 a m

Anomalies and Fractures of the Vertebral Articular Processes (Lantern Demonstration)

WILBUR BAILEY, Los Angeles

Bony Anomalies in Wrist and Foot (Lantern Demonstration)  
W WARNER WATKINS, Phoenix, Ariz

Classification of Lymph Node Enlargements (Lantern Demonstration)  
PLINY F MORSE, Detroit

The Character and Significance of the Blood Picture in the Lymphadenopathies (Lantern Demonstration)  
B K WISEMAN, Columbus, Ohio

The Roentgen Treatment of the So Called Malignant Lymphomas  
F W O'BRIEN, Boston

Leukemia of the Stomach Producing Hypertrophy of the Gastric Mucosa (Lantern Demonstration)  
LEO G RIGLER, Minneapolis

Friday, May 15—9 a m

Election of Officers

Radiation Therapy of the Lip (Lantern Demonstration)

IRA I KAPLAN, New York

Roentgen Rays as an Aid in the Treatment of Gas Gangrene (Lantern Demonstration)  
JAMES F KELLY, Omaha

Roentgen Therapy of Some Acute, Subacute and Chronic More or Less Localized Infections (Lantern Demonstration)  
FRED M HODGES and R A BERGER, Richmond, Va

Cystic Disease of the Lung (Lantern Demonstration)  
J CASH KING and LEO C HARRIS JR, Memphis, Tenn

Needle (Aspiration) Biopsy of Bone Lesions (Lantern Demonstration)  
ROBERT P BALL, Chattanooga, Tenn

Giant Cell Bone Tumor Further Observations on the Response to Surgical and Radiation Therapy (Lantern Demonstration)  
CARLETON B PEIRCE and ISIDORE LAMPE, Ann Arbor, Mich

## SECTION ON MISCELLANEOUS TOPICS

MEETS IN INSIDE COMMITTEE ROOM, FIFTH FLOOR,  
MUNICIPAL AUDITORIUM

### Session on Tuberculosis

#### OFFICERS OF SESSION

Chairman—JAMES ALEXANDER MILLER, New York

Secretary—CHARLES H COCKE, Asheville, N C

Wednesday, May 13—2 p m

Chairman's Address Some Modern Concepts of Tuberculosis  
JAMES ALEXANDER MILLER, New York

Pathogenesis of Tuberculosis (Lantern Demonstration)  
MAX PRINER, Oneonta, N Y

Case Finding Methods for the Diagnosis of Tuberculosis (Lantern Demonstration)  
J BURNS ANDERSON, JR, New York

Sanatorium Care of the Tuberculous  
L S PETERS, Albuquerque, N M

Compression Therapy Uses and Limitations (Lantern Demonstration)  
J J SINGER, St Louis

## THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will occupy the balcony around the exhibition floor of the Kansas City Municipal Auditorium. The same general arrangement of booths and decorations will be carried out as in former years. In addition to the groups of exhibits sponsored by the fifteen sections of the Scientific Assembly, there will be motion picture programs put on by the Sections on Ophthalmology and Orthopedic Surgery, a group of exhibits on traffic accidents and two special exhibits subsidized by the Board of Trustees.

Admission to the Scientific Exhibit will be limited to individuals wearing Fellowship or other badges of the convention and to guests to whom special cards of admission have been issued. The public will not be admitted to the Scientific Exhibit.

Following are the section representatives:

IRVING S. WRIGHT, New York, Section on Practice of Medicine

R. S. DINSMORE JR., Cleveland, Section on Surgery, General and Abdominal

H. CLOSE HFSSELTINE, Chicago, Section on Obstetrics, Gynecology and Abdominal Surgery

GEORGIANA DVORAK-THEOBALD, Oak Park, Ill., Section on Ophthalmology

J. L. MYERS, Kansas City, Mo., Section on Laryngology, Otology and Rhinology

F. THOMAS MITCHELL, Memphis Tenn., Section on Pediatrics

RALPH H. MAJOR, Kansas City, Mo., Section on Pharmacology and Therapeutics

J. P. SIMONDS, Chicago, Section on Pathology and Physiology

PETER BASSOE, Chicago, Section on Nervous and Mental Diseases

C. W. FINNERUD, Chicago, Section on Dermatology and Syphilology

PAUL A. DAVIS, Akron, Ohio, Section on Preventive and Industrial Medicine and Public Health

R. S. FERGUSON, New York, Section on Urology

R. L. DIVELEY, Kansas City, Mo., Section on Orthopedic Surgery

J. A. BARCFN, Rochester, Minn., Section on Gastro-Enterology and Proctology

S. W. DONALDSON, Ann Arbor, Mich., Section on Radiology

## Special Exhibit on Diabetes

The exhibit on diabetes will be carried out again this year along somewhat the same lines as last year. The committee in charge of the exhibit is composed of E. P. Joslin, chairman, Boston, Charles H. Best, Toronto, Louis I. Dublin, New York, Ralph H. Major, Kansas City, Mo., Howard F. Root, Boston, Bernard Smith, Los Angeles, and Russell M. Wilder, Rochester, Minn.

The exhibit will include all phases of the subject under the following headings: laboratory, statistics, pathology, physiology, surgery, diet, diabetic coma, insulin and summer camps for children, state and city diabetic programs.

In addition to continuous demonstrations on the foregoing subjects, there will be a special room set aside for short lectures and conferences of small groups of individuals. An outstanding corps of demonstrators will be on hand continuously throughout the week.

## Special Exhibit on Fractures

The exhibit on fractures is continued again after a lapse of several years. The special exhibit committee appointed by the Committee on Scientific Exhibit of the Board of Trustees for the Kansas City session is composed of Frank D. Dickson,

Kansas City, Mo., Walter Estell Lee, Philadelphia, and Kellogg Speed, chairman, Chicago, assisted by an advisory committee as follows:

ISIDORE COHN,  
New Orleans

H. EARLE CONNELL,  
Fairfield, Ala.

FREDERIC J. COTTON,  
Boston

WILLIAM DARRACH,  
New York

RICHARD B. DILLEHUNT,  
Portland, Ore.

EDRIDGE L. ELIASON,  
Philadelphia

LIO CLOESSER,  
San Francisco

GEORGE W. HAWLEY,  
Bridgeport, Conn.

MELVIN S. HENDERSON,  
Rochester, Minn.

JAMES M. HITZROT,  
New York

WILLIAM L. KELLER,  
Washington, D. C.

ROY D. McCURE,  
Detroit

FRANK R. OBER,  
Boston

DALLAS B. PHEMISTER,  
Chicago

J. SPENCER SPEED,  
Memphis Tenn.

The exhibit this year will be composed of the following subjects:

1. Making and Application of Plaster of Paris
2. Emergency Treatment for Transportation of Fractures of the Lower Extremities
3. Compression Fractures of the Spine
4. Fractures of the Radius—Lower End
5. Fractures of the Metacarpals and Phalanges

Demonstrations will be given continuously throughout the week. A special folder has been prepared for distribution in connection with the exhibit.

The following physicians will take part in the demonstrations:

Bertram S. Adams, Hibbing, Minn.  
R. I. Anderson, Richmond, Va.  
A. E. Bence, Wichita, Kan.  
Guy A. Caldwell, Shreveport, La.  
James J. Callahan, Chicago  
W. B. Carrell, Dallas, Texas  
F. Walter Carruthers, Little Rock, Ark.  
Freemont A. Chandler, Chicago  
Dwight T. Clark, Evanston, Ill.  
E. B. Cudney, Pontiac, Mich.  
Wallace S. Duncan, Cleveland  
John Dunlop, Pasadena, Calif.  
Donald C. Durman, Saginaw, Mich.  
James R. Elliott, Kansas City, Mo.  
C. B. Francisco, Kansas City, Mo.  
Alfred E. Gallant, Los Angeles  
J. A. Green, Rockford, Ill.  
Vernon L. Hart, Minneapolis  
H. Lewis Hess, Kansas City, Mo.  
Paul N. Jepson, Philadelphia  
Fred A. Jostes, St. Louis  
Albert Key, St. Louis  
J. M. King, Pittsburgh  
Marion L. Knefelter, St. Louis

Philip H. Kreuscher, Chicago  
James W. Martin, Omaha  
Duncan C. McKeever, Kansas City, Mo.  
Thomas C. Meany, Chicago  
Frank G. Murphy, Chicago  
W. B. Owen, Louisville, Ky.  
W. J. Potts, Oak Park, Ill.  
Warren R. Rainey, St. Louis  
Wells C. Reid, Goodrich, Mich.  
Dean L. Rider, Riverside, Ill.  
G. R. Rountree, Oklahoma City  
Robert D. Schrock, Omaha  
G. D. Schott, Sullivan, Ind.  
Lemuel D. Smith, Milwaukee  
James E. M. Thomson, Lincoln, Neb.  
Augustus Thorndike Jr., Boston  
Horace E. Turner, Chicago  
D. R. Ulmer, Terre Haute, Ind.  
Charles S. Venable, San Antonio  
Jay D. Byn, Grand Rapids, Mich.  
J. R. Watkins, Alhedeem, Wash.  
George A. Williamson, St. Paul  
W. Eugene Wolcott, Des Moines, Iowa

## SECTION EXHIBITS

## Section on Practice of Medicine

DWIGHT L. WILBUR and ALBERT M. SNELL, Mayo Foundation for Medical Education and Research, Rochester, Minn. *Deficiency states associated with gastro-intestinal diseases.* Exhibit of charts and transparencies showing clinical data, histories and photographs of cases illustrating the importance of abnormalities of the gastro-intestinal tract in production of deficiency and metabolic states.

A. E. BENNETT, C. A. OWENS, PAUL PERSON and BRUCE AUSTIN, University of Nebraska College of Medicine and Lutheran Hospital, Omaha. *Artificial fever therapy by means of Kettering hypertherm.* Exhibit of charts outlining indication and contraindication of artificial fever therapy, various diseases under experimental study, management of syphilis by combined fever and chemotherapy compared with malarial therapy, results of gonorrheal infections, arthritis and miscellaneous disorders. Photographs illustrating temperature elevation used in treatment, thermometric gradient fever studies of various tissues of the body, case studies showing results obtained in various diseases, thermal death time studies in meningococci.

WILLIAM A. GROAT and STELLA M. ZIMMER, Syracuse University, Syracuse, N. Y. *Basophilic leukemia* Exhibit of photomicrographs, natural color photomicrographs and statistical charts and graphs on studies of the blood and of bone marrow obtained by biopsy and autopsy from a case of acute myeloid leukemia with extreme basophilia (acute basophilic leukemia), also demonstrations of studies of so-called chronic basophilic leukemia and of the basophilic myelocytes, hemoblasts of Ferrata and of Di Guglielmo found in chronic myeloid leukemias generally.

J. DEWEY BISGARD and JOHN C. SHARPE, University of Nebraska College of Medicine, Omaha. *Studies in hematology* Exhibit of complete cytologic studies of the blood of (1) normal rabbits used as controls, fed with thyroid and administered liver by muscle mouth and vein, (2) totally thyroidectomized adult rabbits with anemia of myxedema, after thyroid feeding, and administered liver by muscle and vein, (3) totally thyroidectomized (cretins), including in all groups reticulocyte responses and hematocrit readings (4) illustrations of Wintrobe hematocrit tube and a chart for rapid and simple computation of results.

N. S. DAVIS III, Department of Pathology, Northwestern University Medical School, Chicago. *The incidence of arteriosclerosis in a large number of necropsies* Exhibit of charts illustrating the gross and age incidence of arteriosclerosis of the aorta, coronary arteries, arteriosclerotic heart disease, coronary thrombosis, arteriosclerotic and arteriosclerotic changes in the kidneys, cerebral hemorrhage and thrombosis in a large number of necropsies, and the importance of arterial disease or its results as a primary or contributory cause of death.

JOSEPH F. ELSEN, The Bronx Hospital, New York. *Bacillary dysentery, distal ileitis, chronic ulcerative colitis and nonspecific intestinal granuloma. Their common pathogenesis* Exhibit of a clinical, epidemiologic, bacteriologic, serologic and pathologic study, tracing the transition stages from acute bacillary dysentery to chronic distal ileitis, chronic ulcerative colitis and nonspecific granuloma. Typical and atypical forms of acute bacillary dysentery are described as well as the results of follow-up studies with special reference to the development of late lesions. One major epidemic (Flexner type of dysentery) and several minor outbreaks (Flexner and Sonne Duval types of dysentery) are included in this study together with practical application of this work in diagnosis and treatment.

W. F. HAMILTON, R. A. WOODBURY and H. T. HARPER, University of Georgia School of Medicine, Augusta. *Optical recording of human blood pressure* Exhibit of a manometer with complete set of auxiliary devices for showing how it works, also charts showing human and comparative blood pressure tracings.

ALAN L. BARACH, Presbyterian Hospital, New York. *The role of helium and oxygen in various types of dyspnea* Exhibit of charts and motion pictures showing the pathophysiology of pulmonary ventilation in severe continuous asthma, emphysema, pulmonary fibrosis, passive pulmonary congestion in heart failure, modification or relief obtained by inhalation of gas mixtures rich in helium or in oxygen, reduction of pathologically elevated intrapleural negative pressures with prevention or alleviation of edema in the lungs.

O. H. ROBERTSON and W. D. SUTLIFF, Department of Medicine, University of Chicago, Chicago. *The lesion of lobar pneumonia: a clinical and experimental study* Exhibit is divided as follows: 1. Early diagnosis shown by roentgenographic evidences and charts of physical signs in lobar pneumonia less than twenty-four hours after onset. 2. Evolution of consolidation shown by roentgenographic observations during the course of the disease in human beings. 3. Gross and microscopic lesions illustrating method of production of experimental lobar pneumonia in dogs. 4. Factors in recovery from lobar pneumonia in men and dogs. Schematic relationship of serum antibodies to the course of the disease. Photomicrographs illustrating the activity of polymorphonuclear phagocytes and macrophages in the clearing of focal lesions.

WILLIAM W. DUKE, Kansas City, Mo. *Thermophilus and actinophilus* Exhibit of motion pictures and photographs demonstrating abnormal reactions to the effect of heat and effort to light, together with etiologic and pathologic bases for a large proportion of cases of this description.

RUSSELL L. HADEN, Cleveland Clinic, Cleveland. *Mechanism of anemia* Exhibit of charts illustrating blood formation, circulation and destruction in all types of anemia, and natural color photomicrographs illustrating all variations of the red blood cells and all types of anemia.

GEORGE L. WALDBOTT, Detroit. *Allergic shock* Exhibit demonstrating its mechanism, factors determining its manifestations and clinical course, tabulation of clinical records of shock induced by means other than injection, photomicrographs of autopsy appearances of shock following injections, ingestion of food, inhalation of air-borne substances, differential diagnosis, laboratory studies during shock, prevention and treatment.

HENRY H. TURNER, University of Oklahoma School of Medicine, Oklahoma City. *Clinical and experimental endocrinology* Exhibit of photographs illustrating the various accepted types of endocrinopathies and results of treatment with some of the newer pituitary fractions: the effects of anterior pituitary growth hormone on pituitary dwarfism; the effects of the anterior pituitary sex hormones on genital aplasia associated with adipsogenital syndrome; the effects of the anterior pituitary-like principles on the descent of testes in patients with cryptorchism; the effect of partial adrenal resection, denervation and splanchnic section on patients with the pituitary-adrenogenital syndromes, or so-called pituitary basophilism of Cushing; the effect of the anterior pituitary adrenotropic factor on a patient with Addison's disease; numerous other clinical endocrinopathies.

EDWARD F. HARTUNG, JOHN CURRENCE, JOHN STUMP, JOHN STAGE DAVIS, OTTO STEINBOCKER and JOSEPH KOVACS, Arthritis Clinic, New York Post Graduate Medical School and Hospital, Columbia University, New York. *Chronic arthritis* Exhibit dealing with research on the blood in arthritis, especially the filament-nonfilament count, agglutinin and precipitin, plasma cholesterol, serum calcium, albumin globulin ratio, gastrointestinal factors in arthritis, especially teeth, gastric acidity, gallbladder and colon, postural corrections, especially of visceroptosis, the prevention of deformities, physical therapeutic measures.

R. FRANKLIN CARTER, CARL H. GREENE, J. RUSSELL TWISS, New York Post Graduate Medical School and Hospital, Columbia University, New York. *Types of gallbladder and liver disease and of associated jaundice* Exhibit of charts, models and drawings demonstrating distinct types of gallbladder disease together with records of cases from the clinic, models and drawings of conditions with associated jaundice with case records from the clinic, motion pictures of normal and pathologic physiology of the gallbladder.

ROBERT M. STECHER, Department of Medicine, Western Reserve University Medical School and City Hospital, Cleveland. *Arthritis of the hand* Exhibit of photographs and roentgenograms of the hand demonstrating different types of arthritis and some other diseases which at times may be confused with arthritis. The characteristic appearances as well as atypical changes due to these diseases are shown, with special emphasis on the time element in these changes.

#### Section on Surgery, General and Abdominal

H. S. PLUMMER, W. M. BOOTHBY, S. F. HAINES, J. DEJ. PEMBERTON, E. C. KENDALL, W. A. PLUMMER, W. C. MACCARTY, R. M. TOVELL and A. H. BULBULIAN, Mayo Clinic, Rochester, Minn. *Diseases and functions of the thyroid gland* Exhibit shows the important contributions to the present knowledge of diseases of the thyroid gland: presents statistical data in graphic form dealing with the occurrence, frequency and mortality of the disease and the results of medication and surgery; includes color photographs and life masks of patients with myxedema before and after treatment and photographs and motion pictures of patients with exophthalmic goiter showing the results of medical and surgical treatment; includes samples of material illustrating important steps in the separation of thyroxine from thyroid glands; models illustrating the surgical anatomy of the thyroid gland; motion pictures and drawings illustrating important steps in partial thyroidectomy with methods of preserving the recurrent laryngeal nerve and parathyroid glands; colored wax casts and photomicrographs of specimens showing the pathology of the thyroid gland and demonstration, by means of models, photographs

and motion pictures, regional methods of anesthesia for thyroidectomy

JOHN O BOWER, J C BURNS and H A MENGLE, Department of Research Surgery, Temple University School of Medicine and General Hospital, Philadelphia *Treatment of spreading peritonitis complicating acute perforative appendicitis* Exhibit of drawings illustrating steps in operative technic and pathologic changes, charts depicting mortality delay, mortality-laxatives, antibody content of convalescent serum, bacteriology of spreading peritonitis and blood mixture in spreading peritonitis charts showing results of treatment of spreading peritonitis by perfringens antiserum, lyophilized convalescent serum, immediate and delayed operation photographs and microscopic slides of sections of appendiceal abscesses, display of therapeutic technic and appliances, lyophilized serum and apparatus for administering dextrose solution intravenously, motion pictures showing operative technic in human beings, operative technic in animals intestine under influence of laxatives, pigeon testing for antibody content of convalescent blood, and venesection and intravenous infusion of dextrose

CHARLES S WHITE and J LLOYD COLLINS, George Washington University School of Medicine, Department of Surgery, Washington, D C *Treatment of empyema* Exhibit of an illuminated model illustrating the open treatment of empyema after the method described by Connors, charts and motion pictures of resection of ribs, packings and redressings

J ROSS VEAL, Louisiana State University School of Medicine, New Orleans *Arteriography and venography in peripheral vascular diseases* Exhibit of selected arteriographs and venographs from a study of many cases of peripheral vascular diseases, including senile arteriosclerosis, Buerger's disease, scleroderma, frost bite, congenital arteriovenous anastomosis, aneurysms, axillary vein thrombosis, intermittent claudication, gangrene and varicose veins Normal arteriographs and venographs of each region are used for comparison with the pathologic states The technic of arteriography is illustrated by motion pictures

CHARLES B HUGGINS, W J NOONAN and B H BLOCKSON, Department of Surgery, University of Chicago, Chicago *Distribution of red and yellow bone marrow and the reticulo-endothelial system in the bone marrow* Exhibit of cleared gross specimens of animals showing distribution of the reticulo-endothelial system in the bone marrow indicating that a single plan of arrangement for the blood forming system runs through these various species, results of experiments showing how the reticulo-endothelial system is caused to increase and fatty marrow to decrease, charts and photographs showing the temperature relationships in bone marrow and the development of the homeothermous state in the albino rat

W W BUCKINGHAM, Kansas City Municipal Tuberculosis Hospital, Kansas City *Surgical collapse in pulmonary tuberculosis* Exhibit of preoperative and postoperative roentgenograms of chest showing indications for and results obtained with the following surgical procedures phrenicotomy (temporary and permanent), pneumolysis (open and closed), plumbage (paraffin packs), thoracoplasty (partial anteriolateral and complete), combinations of the foregoing procedures

J W CUTLER, Henry Phipps Institute, University of Pennsylvania, Philadelphia *Pneumolysis—single cannula technic* Exhibit of instruments roentgenograms and models of characteristic adhesions complicating artificial pneumothorax therapy in pulmonary tuberculosis demonstration of instruments for severing adhesions complicating pneumothorax therapy through a single opening into the chest

R RUSSELL BEST, FREDERICK HICKEN and HOWARD B HUNT Departments of Anatomy, Surgery and Roentgenology University of Nebraska College of Medicine Omaha *Cholangiographic studies of the gallbladder and biliary ducts* Exhibit showing technic of making cholangiograms at operating table by motion picture and color transparencies anatomy and histology of common duct cholangiograms demonstrating spasm of lower end of common duct cholangiograms taken at the operating table and following operation aiding in the diagnosis of biliary tract lesions mouldage display of organic obstructive lesions of the biliary tract

EARL A GRAHAM and J J SINGER Barnes Hospital St Louis *Chest tumors and cysts* Exhibit of roentgenograms,

photographs, drawings, pathologic specimens, charts and short case histories showing different types of chest tumors and cysts with diagnostic procedures, types of operations, and so on

ALFRED A STRAUSS, Chicago *Surgical diathermy for carcinoma of the stomach and rectum* New methods of radical surgical procedures for carcinoma of colon and stomach Exhibit of wax models showing the newly devised instruments for surgical diathermy of both the stomach and the rectum, with a machine to illustrate its use, wax models of specimens removed, histologic slides and photographs showing the changes that go on in the carcinoma cells and surrounding area from surgical diathermy and the effect on the reticulo-endothelial system which probably accounts for the immunity produced against carcinoma by this method, drawings and photographs of the technic of ileostomy for removal of rectosigmoid carcinoma, the use of the ileostomy in perforating diverticulitis of the sigmoid and ulcerative colitis, wax models of specimens removed

G M DORFANCE, Saint Agnes Hospital, Philadelphia *Treatment of fractures of the femur in children by means of elevation of the bed approximately 45 degrees* Exhibit of bed with patient in place, roentgenograms showing after-treatment and follow up

ARNOLD S JACKSON, Jackson Clinic, Madison, Wis *Diseases of the thyroid gland* Exhibit of slides illustrating various types of colloid, adenomatous, nontoxic and toxic intrathoracic and exophthalmic goiter, malignant conditions including sarcoma and carcinoma, iodine hyperthyroidism, cretinism, myxedema and photomicrographs of the various pathologic conditions of the thyroid gland, charts illustrating sources of error in basal metabolic rates, distribution of cretinism, study of large number of cases of toxic adenoma as regards cardiac and other observations, gross pathologic specimens, display of instruments used in thyroidectomy, display of 'patent medicine' cures for goiter and colored motion picture of technic of thyroidectomy

CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM, K J HEVICHSEN, Chicago *Collapse therapy in pulmonary tuberculosis* Exhibit of roentgenograms of the chest before and after collapse therapy by various methods, pneumothorax, intrapleural pneumolysis, phrenicectomy and thoracoplasty, demonstration of surgical technic by motion pictures, charts illustrating relative end results in collapse therapy

#### Section on Obstetrics, Gynecology and Abdominal Surgery

RUSSELL VON L BUNTON and HERMAN A SHELANSKI, Philadelphia General Hospital, Philadelphia *Study of the incidence of Trichomonas vaginalis infection in a series of cases, with cultural characteristics of the organism and results of a form of treatment* Exhibit of charts, dealing with the incidence of Trichomonas vaginalis infection and the incidence in male prostatic secretion, method of culture of the parasite together with a microscopic demonstration of the parasite, results obtained by using silver picrate in kaolin as a therapeutic agent

WILLIAM B THOMPSON, The William E Branch Clinic, Los Angeles *Cesarean section in Los Angeles County for 1934-1935* Exhibit of charts dealing with an analysis covering all abdominal deliveries done in 119 hospitals and maternity homes, incidence, the indications of the duration of labor and of rupture of membranes with their relation to mortality and morbidity for both classic and low cervical sections, percent ages of deliveries conducted by doctors of medicine, osteopaths, chiropractors midwives and others percentage of cesarean sections and the mortality for each group

WILLIAM F MENGERT and E W SCHELDROP, University Hospitals, Iowa City *Mechanics and anatomy of uterine support* Exhibit of colored motion pictures depicting descent of the uterus in a warm cadaver and during vaginal hysterectomy in the living as the various supporting structures are cut charts showing results of similar experiments on cadavers, pelvic cross coronal and sagittal section of the adult female pelvis with accompanying descriptive charts, similar sections of female fetuses with descriptive charts

E C HAMBLIN and B CARTER Department of Obstetrics and Gynecology Duke University Hospital and School of

Medicine Durham, N C *Studies of the endometrium in functional abnormalities of menstruation and its response to endocrine therapy* Exhibit of water color diagrams presenting concepts of the hormonology of menstruation, photomicrographs illustrating studies of the endometrium in menometrorrhagia, menorrhoea and other functional disorders of menstruation, effects of certain types of endocrine therapy on the endometrium in these conditions

W E CALDWELL, HOWARD C MOLOY and D A D'ESORO Sloane Hospital for Women and Department of Obstetrics and Gynecology, Columbia University, and Roentgen Ray Department Presbyterian Hospital, New York *Clinical and roentgenologic recognition of anatomic variations in female pelvis and their obstetric significance* Exhibit of illustrations of pelvic variations and the mechanism of labor with precision stereoscope to demonstrate the roentgenologic technic advised

#### Section on Ophthalmology

BERTHA A KLIEN Rush Medical College Chicago *Malformations of the human eye* Exhibit of illustrations of clinical observations and photomicrographs of histologic details of malformations of the human eye, including atypical colobomas of the choroid the superior conus, aberrant nerve fibers colobomas and grooves of the optic nerve, orbital appendices of the sheaths of the optic nerve, aberrant retinal vessels and microphthalmus

ALBERT L BROWN, Children's Hospital Research Foundation, Cincinnati *Experimental uveitis and corneal ulcers* Exhibit of gross specimens, photographs and photomicrographs showing uveitis produced in rabbits' eyes, corneal ulcers produced in rabbits' eyes, showing ulcers in untreated animals and in animals treated with parenteral administration of typhoid vaccine with and without aspiration of the anterior chamber to increase intra ocular antibody concentration

BRITTAIN F PAYNE and CONRAD BERENS, Lighthouse Clinic, New York *Certain phases in the development of the eye in the human embryo* Exhibit of a series of specimens of human embryos demonstrating the formation of the primary optic vesicle and invagination of the surface ectoderm to form the crystalline lens and the development of the secondary optic vesicle, further development of the human eye demonstrated by various intermediate states up to term

LAURENCE D REDWAY, Institute of Ophthalmology, Presbyterian Hospital, New York *Color photography of the human eye and adnexa* Exhibit of colored transparencies of the external eye and of the fundus oculi, both normal and pathologic

ARTHUR J BEDELL, Albany, N Y *Modern photography of the eyes* Exhibit of photographs of the external diseases of the eye in black and white colored and infra-red, newest developments in fundus photography plain and colored plates

A E BRALEY, State University of Iowa, College of Medicine, Iowa City *Tumors of the eyelids* Exhibit of transparent colored photographs and stereophotographs of tumors of the eyelid, charts showing frequency, location and differential diagnosis

PHILLIPS THYGESON and FRANCIS I PROCTOR, University of Iowa, Iowa City *Differential diagnosis of trachoma* Exhibit of colored drawings and photographs illustrating clinical appearance and pathology of the conjunctiva and cornea in the various stages of trachoma, biomicroscopic appearance of trachomatous keratitis, clinical points and laboratory observations useful in the differential diagnosis of trachoma from follicular conjunctivitis, folliculosis, ocular peniphagus and other conjunctival diseases

EDWIN M NEHER, Research Department University of Utah, Salt Lake City *Origin of spectacle or brille in the rattlesnake* Exhibit describing the embryology of the snake's eye with special reference to the origin of the spectacle secondary features added to the basic vertebrate eye according to the habits environment and requirements of the various animals, the brille, or spectacle, is a secondary feature which has been added for the protection of the snake's eye

EDMUND B SPAETH, Graduate School of Medicine University of Pennsylvania, and Wills Eye Hospital Philadelphia *Ophthalmic plastic surgery* Exhibit of photographs illustrating ophthalmic plastic cases before and after correction

J E SMITH, C E RICE and HARVEY D LAMB, Missouri Trachoma Hospital Rolla, Mo *Histology and therapeutics of trachoma* Exhibit of photomicrographs and microscopic sections dealing with histology of trachoma, especially emphasizing histology of corneal trachoma, histology of tear sacs removed in trachoma patients, the caruncle and the caruncle area, and of the tarsus removed in tarsectomy operations, study of the Von Prowazek-Halberstaedter inclusions of trachoma through photographs and mounts, therapeutic side of trachoma, statements of histories

ALAN C WOODS FRANK B WALSH and TULLOS O COSTON, Wilmer Ophthalmological Institute, Johns Hopkins Hospitals and University Baltimore *Photography of the eye* Exhibit of motion pictures of eye operations, colored stereoscopic plates and paintings of external eye and fundus conditions

#### MOTION PICTURE PROGRAM

The following motion pictures will be shown on a definite schedule in an area adjacent to the exhibits of the Section on Ophthalmology

RAMON CASTROVIEJO, New York Keratoplasty

RAY K DAILY, Houston, Texas Cataract Extraction

WALTER H FINK, Minneapolis The Management of Strabismus

J O McREYNOLDS, Dallas, Texas Ophthalmic Operations in Color

J E SMITH Rolla, Mo Trachoma in the Native White Population of the United States

CHARLES N SPRATT, Minneapolis Eye Operations

CLIFFORD B WALKER, Los Angeles Combined Galvanic and Diathermic Treatment of Separated Retina

#### Section on Laryngology, Otology and Rhinology

RAPHAEL SCHILLINGER, Brooklyn *Roentgenologic aspects of mastoiditis* Exhibit of roentgenograms of the mastoid bone showing anatomic classification, bone specimens, charts and drawing demonstrating importance of this anatomic classification in predicting the course of the disease, roentgenograms of pathologic mastoids with discussion of film interpretation, case histories and operative data roentgenograms of pathologic mastoids treated by roentgen irradiation, showing the value of the roentgen ray as a therapeutic agent, discussion of 'syndrome of favorable action' as an indication for this type of therapy, limitations of this method of treatment, use of roentgen irradiation in the treatment of otitis media as a prophylaxis against mastoiditis

M F ARBUCKLE, St Louis *Diagnosis and treatment of diseases of the pulmonary tract and esophagus* Exhibit demonstrating methods employed in the study of disorders of the pulmonary tract and esophagus for the purpose of diagnosis and application of therapeutic measures with particular reference to the results of physical radiologic and direct endoscopic examination, examples of disorders of the pulmonary tract, such as lung abscess, bronchiectasis, tumors, congenital lesions, impacted foreign body, both opaque and nonopaque, and esophageal disorders, such as congenital or acquired lesions, malignant disease and impacted foreign body

L W DEAN, ARTHUR W PROETZ C C BUNCH, LOUIS J BIRNBERGER JAMES B COSTEN, LOUIS K GUGGENHEIM DOROTHY WOLFF and HARRY N GLICK Department of Otolaryngology, Washington University School of Medicine, St Louis *The pathologic and normal gross and microscopic anatomy the embryology of the ear nose pharynx and larynx* Exhibit of gross anatomic specimens of the nose pharynx larynx and ear cadaver specimens illustrating operations on the ear nose and throat, gross and microscopic specimens showing normal and pathologic anatomy of the ear, embryologic specimens of the ear, nose and throat, transparent reconstruction of the spiral ganglion

#### Section on Pediatrics

C ULYSSES MOORE, Portland, Ore *Variation in development found in a rickets survey* Exhibit showing a study of preschool children and the new-born, clinical, laboratory, roentgenologic and photographic observations, comparison of osseous development of twins

I NEWTON KUGELMASS, New York *Modifying milk for infants digestion* Exhibit showing graphic interpretation of

experimental and clinical studies of milk physiology in infant feeding involving the mechanism of milk clotting, the character of curd formation, the index of milk digestibility, the adaptation of milk to infants' digestion, the relation between milk digestion and infant constitution, the biochemical evaluation of milk digestion in vivo and in vitro correlated with normal and artificial feeding

ARCHIBALD L HOYNE, Municipal Contagious Disease Hospital Board of Health and Cook County Hospital, Chicago, and N S FERRY, Parke, Davis & Co, Detroit *Meningococcus antitoxin* Exhibit of graphs, charts and photographs illustrating research development and clinical application of meningococcus antitoxin starting with the growth of cultures and carrying the exhibit through the preparation of toxin in flasks, tests of toxin, tests on antitoxin and finally giving the therapeutic results on the human being

PERCIVAL NICHOLSON WALTER ESTELL LEE and MAX M STRUMIA, Bryn Mawr Hospital Bryn Mawr, Pa *Mechanical lesions of the appendix as a cause of appendicitis* Exhibit of charts showing the results of clinical and anatomic examinations of a number of appendicitis cases in children, emphasizing the importance of mechanical obstruction to the lumen as etiologic elements of appendiceal colic

GEORGE M LYON Cabell County Medical Society and Board of Education of Cabell County, Huntington, W Va *Medical participation in a school health program* Exhibit showing a plan of medical participation in the county wide school program as carried on in Cabell County of West Virginia by the Committee on School Health Problems of the Cabell County Medical Society

JULIAN D BOYD and C L DRAIN, State University of Iowa, Iowa City *Nutrition and the teeth* Exhibit of observations correlating the resistance of tooth decay with the diet habits of the individual, data concerning the oral flora, the mineral metabolism and intrinsic tooth structure as related to resistance or susceptibility of tooth decay, data indicating a close relationship between the resistance of teeth to decay and the general level of health of the individual with diet playing an outstanding part in the maintenance of each

S D KRAMER, Long Island College of Medicine, Brooklyn *Poliomyelitis—epidemiology, pathology and immunity* Comparative study of the value of several methods for active immunization Exhibit demonstrating by means of charts and graphs the experimental evidence on which the concepts of the disease are based, clinical understanding of the disease is fairly clear, as are some of the epidemiologic concepts but a number of these concepts are based on extremely sparse data, and an effort is made to add to these data, the enthusiasm recently aroused in active immunization against the disease has made a comparative study of a number of methods for active immunization against the disease imperative, no proved method available for active immunization against poliomyelitis, two proved instances of survival of virus in the nasal secretions thirteen to sixteen days after onset of illness are illustrated

A W SNOOK, Stanford University Hospitals, San Francisco *Stages duration and prognosis of glomerular nephritis in childhood* Exhibit of colored charts showing typical microscopic urinary sediments in the initial, latent degenerative and terminal stages of glomerular nephritis, charts showing the Addis classification of glomerular nephritis with various possibilities that may occur after the onset of the initial stage specimens of the Addis tubes for albumin determination and sediment counts

JESSE R GERSTLEY KATHARINE M HOWELL and DAVID J COHN Michael Reese Hospital, Chicago *The infant stool* Exhibit of charts tables, drawings, cultures, microscopic slides under the microscope and models showing effect of different carbohydrates on the infant stool, as well as their effect on metabolism of calcium and phosphorus

#### Section on Pharmacology and Therapeutics

UNITED STATES DEPARTMENT OF AGRICULTURE, BUREAU OF CHEMISTRY AND SOILS, Washington, D C *Medical products from mold fermentation fruit juice, selenium cottonseed meal determination of gossypol for toxicity and biologic values* Exhibit of bottles of products, specimens, charts, diagrams, flow sheets, and other material

BUREAU OF ENTOMOLOGY AND PLANT QUARANTINE *Screw worm myiasis of men and animals and the therapeutic use of surgical maggots and their excretion* Exhibit of colored bromide enlargements and paintings of the various stages of the screw worm fly, cases of screw worm infestation in man and various animals and scenes indicating the methods of treatment or control advocated by the bureau, equipment, photographs and charts illustrating investigational work on the therapeutic use of maggots and their excretions

L G ROWNTREE, J H CLARK, ARTHUR STEINBERG and N H EINHORN, Philadelphia Institute for Medical Research, Philadelphia, and A M HANSON, Fairbault, Minn *The role of the thymus and pineal glands in growth and development* Exhibit of charts, photographs, cages with rats, motion pictures and slides showing the role of the thymus and pineal glands in growth and development

A G BELTMAN, Department of Surgery, University of Oregon Medical School, Portland, Ore *The tannic acid silver nitrate treatment for burns* Exhibit of charts and photographs showing in detail the method of application of the treatment and showing its points of superiority, charts showing laboratory work, photographs depicting plastic reconstruction following burns, other interesting features of plastic surgery

WILLARD O THOMPSON, ARTHUR DEAN BEVAN, NORRIS J HECKEL, PHEBE K THOMPSON and SAMUEL G TAYLOR III, Chicago *Glands of internal secretion* Exhibit of charts and photographs covering recent original work on the pathologic physiology of the thyroid, the pituitary gland, including the calorogenic activity of the anterior lobe the nature of Addison's disease and its treatment with an active adrenal cortex extract, anomalies of sex organs, including a consideration of the effect of anterior pituitary-like substance on undescended testicles, and prostatic implants in the anterior chamber of the eye

ARTHUR C CLASEN, Kansas City, Mo *Blood amylase, lipase and phosphatase determinations in hepatic and pancreatic disturbances* Exhibit of charts and graphs showing blood amylase and lipase curves in experimental pancreatitis, also amylase, lipase and phosphatase curves in clinical cases of liver diseases

BAYARD T HORTON, GEORGE E BROWN\* and GRACE ROTZ, Mayo Foundation for Medical Education and Research Rochester, Minn *Hypersensitiveness to cold* Exhibit of a clinical and experimental study illustrating the various phases of hypersensitiveness to cold, the local and systemic manifestations constitute distinct clinical syndromes 1 Those in which the manifestations, both local and general suggest those produced by histamine 2 Those in which paroxysmal hemoglobinuria and vasomotor and agglutinative features are outstanding Experimental work gives evidence of the chemical nature of these reactions, patients of both groups are amenable to treatment by desensitization to cold

#### Section on Pathology and Physiology

G C SUPPLEE and S ANSBACHER, Research Division, The Borden Company, New York *Pure lactoflavin, an entity of the water soluble vitamin B complex* Exhibit of specimens of pure crystalline lactoflavin as isolated from milk, properly equipped with a source of radiation revealing invisible ultraviolet rays only showing solutions of known and pure lactoflavin exposed alternately to invisible ultraviolet rays and natural light thereby, permitting visual instruction regarding the fluorescent characteristics of lactoflavin and adaptation of the fluorescent principle as a means of quantitative estimation

THE ARMY MEDICAL MUSEUM Office of the Surgeon General United States Army, Washington, D C *Color photography* Exhibit of three color separation photography of gross and microscopic material to record the natural color in medical subjects, method of preparing prints lantern slides and transparencies, with actual demonstration of printing the three colors and combining them to make complete prints

JULIUS S WEINGART, Des Moines, Iowa *The technique of the postmortem examination* Exhibit of charts and motion pictures showing the best technique for postmortem examination the proper type of instruments to be used the importance of study of the gross anatomic changes, methods of facilitating restoration of the body etc

\* Deceased

REUBEN L. KAHN, University Hospital, Ann Arbor, Mich. *Tissue immunity* Exhibit of charts presenting results of experiments on tissue immunity, illustrating the immunologic role of the tissues in the nonimmune state, the period of incubation and the immune state, the role of the tissues in active and passive immunity, the relation between tissue immunity, and humoral immunity, immunity in the adult and in the young.

HARRY C. SCHMEISSER and JOSEPH L. SCIANNI, University of Tennessee Pathological Institute, Memphis. *The dignity of the autopsy* A photographic exhibit in four sections: 1. History of the autopsy from antiquity to the nineteenth century; 2. History of the autopsy from the nineteenth century to date; 3. Autopsy of today; 4. Uses of the autopsy.

ARTHUR F. ABT, CHESTER J. FARMER and ELIZABETH SMITH, Northwestern University Medical School, Chicago. *Metabolism of cevitamic acid of infants and children* Exhibit of charts showing normal values for reduced cevitamic acid in the blood plasma of infants and children from birth to 13 years of age, correlation of these determinations with capillary skin fragility values, cases of subclinical scurvy and of active scurvy with values for blood plasma, urinary excretion and capillary skin tests, a microchemical method for cevitamic acid determinations, tolerance tests obtained by using this method, apparatus for determining capillary skin fragility, pictures of active and healing scurvy treated with cevitamic acid.

E. SPIEGEL, M. SPIEGEL-ADOLF and M. G. WOHL, Temple University School of Medicine, Philadelphia. *New biophysical methods* (a) Galvanometric determination of hyperalgetic zones. Exhibit showing that in visceral pain the spinal cord segments receiving impulses from diseased internal organs are in a state of hyperexcitation, as is manifested by increased potentials in the corresponding dermatomes. Demonstration of measurement of skin potentials and charts illustrating results. (b) Measurement of convulsive reactivity. Determination of minimal energy necessary to produce convulsions in animals, effect of various drugs.

ROY R. KRACKE and HORTENSE GARVER, Emory University, Ga. Blood dyscrasias with particular reference to leukocyte types. Exhibit of colored drawings showing the individual leukocyte types of normal and abnormal blood with colored plates of groups of pathologic cell types, plates illustrating the blood pictures of the various blood dyscrasias with typical and atypical phases, charts showing descriptions of the various hematologic pictures seen in blood diseases, microscopic demonstration of the rare type of leukemias.

MAX CUTLER and OTTO SAPHIR, Tumor Clinic and Department of Pathology, Michael Reese Hospital, Chicago. *Transferring tumor cells during biopsy on malignant tumors* Exhibit of photographs, photomicrographs, models, diagrams, lantern slides and motion pictures, illustrating the transference of tumor cells during biopsy, with special reference to carcinoma of the breast, surgical technique, special staining methods to illustrate presence of tumor cells on knife blades, models of breasts showing lines of recurrence and their relationship to this subject.

#### Section on Nervous and Mental Diseases

GROVES B. SMITH, Beverly Farm, Inc., Godfrey, Ill. *Mental hygiene in relationship to general practice* Exhibit of graphs and charts illustrating the problems of general practice so far as neuropsychiatric and mental hygiene aspects are concerned, diagnostic procedures, community responsibilities, importance of economic relationship.

HENRY NEWMAN, Stanford University School of Medicine, San Francisco. *Neurologic diagnostic instruments* Exhibit of a portable chronaximeter and an instrument for accurate determination of vibratory sensibility, demonstration together with charts showing the circuits employed and details of construction.

ERNEST SACHS and LEONARD T. FURLOW, Washington University School of Medicine, Barnes and St. Louis Children's Hospitals, St. Louis. *Brain and spinal tumors in patients who are non-specific from symptoms* Exhibit of pathologic specimens of brain and spinal cord tumors, clinical abstract of each case, pathologic diagnosis with roentgenograms.

FREDERIC A. GIBBS, WILLIAM G. LENOX, HALLOWELL DAVIS, ERNA L. GIBBS and ALBERT GRASS, Harvard Medical School, Boston. *The electro-encephalogram and its application to the*

*study of epilepsy* Exhibit showing graphic recording of the electrical potentials of the brain of a human subject by an apparatus similar to the electrocardiograph except that there is higher amplification of the electrical potentials, and records are made by means of an ink-writing pen on a moving paper tape, apparatus will be attached to a subject and continuous records made demonstrating the type of wave to be seen in conditions of normal cerebral activity and as a result of certain physiologic alternations, records of pathologic conditions, especially epileptic seizures, will be shown.

W. JAMES GARDNER, Neurosurgical Division, Cleveland Clinic, Cleveland. *Hereditary brain tumors* Exhibit of an elaborate family tree of five generations of more than 200 members demonstrating the transmission of these tumors as true mendelian dominants affecting some thirty-seven members, case reports of the affected members, autopsy material from four verified cases with microscopic studies of a fifth case specimen from a patient with bilateral acoustic tumors, consisting of serial sections through the entire head, demonstrating the location of these tumors.

#### Section on Dermatology and Syphilology

R. A. VONDERLEHR, Division of Venereal Diseases, United States Public Health Service, Washington, D. C. *Untreated syphilis in the male Negro. A comparative study of treated and untreated cases* Exhibit records the results of the examination of a group of syphilitic male Negroes who have never received modern treatment for their infections, compared with a group of presumably nonsyphilitic Negroes from the general population in the same area. Original observations included thorough clinical, roentgenologic and laboratory studies to ascertain the extent of the involvement of the various organs and structures of the human body in the late syphilitic process, comparison of groups of Negroes who have received adequate and inadequate treatment, a comparative analysis of the outcome in treated and untreated cases.

HAMILTON MONTGOMERY, Mayo Clinic, Rochester, Minn. *Histopathology of various types of cutaneous tuberculosis* Exhibit of colored photomicrographs and schematic drawings illustrating the pathologic differences between various types of cutaneous tuberculosis, charts on the classification of tuberculosis and on the pathology of the conditions.

THEODORE CORNBLEET, Chicago. *Pigment and vitamin C* Exhibit of charts illustrating that vitamin C in the skin is intimately associated with pigment and does not seem capable of remaining as such in the skin without the presence of pigment, vitamin C absorbs the actinic or pigment producing rays and in this process is used and converted into a new product, it appears that pigment furnishes an anchor to vitamin C, which in turn is an effective shield against photochemical injury.

GEORGE M. MACKEE and ANTHONY C. CIPOLITARO, Skin and Cancer Unit, New York Post Graduate Medical School and Hospital, Columbia University, New York. *Cutaneous tuberculosis and tuberculids* Exhibit of colored photographs illustrating all clinical varieties of skin tuberculosis and tuberculids.

FRED WISE and CHARLES R. REIN, Skin and Cancer Unit, New York Post Graduate Medical School and Hospital, Columbia University, New York. *Lichen ruber monileformis* Exhibit of wax models, illuminated photographs, ordinary photographs, microscopic sections, and the like on lichen ruber monileformis.

GEORGE M. LEWIS and MARY E. HOPFER, Skin and Cancer Unit, New York Post Graduate Medical School, Columbia University, New York. *Treatment of ringworm of the scalp* Exhibit of photographs and charts illustrating the various diagnostic and therapeutic measures necessary for the competent management of tinea capitis, cultural determination of the causative fungus, experimental data embodying biologic and immunologic concepts.

SAUEL AYRES, JR., NELSON PAUL ANDERSON and PAUL D. FOSTER, Los Angeles. *Dermatologic versus surgical treatment of carbuncles and furuncles* Exhibit of charts, diagrams and photographs illustrating a clinical and statistical study of the methods of treating furuncles of the face and carbuncles, as commonly practiced by dermatologists and by surgeons, with especial reference to technique, duration of illness, cosmetic results and mortality.

### Section on Preventive and Industrial Medicine and Public Health

FRED E. ANGLE, WILLIAM H. ALGIE and S. J. SCHILLING, Kansas City, Kan. *Bruce's disease in man (undulant fever) and in animals (Bang's disease)* Exhibit of charts, colored photographs, drawings, pathologic specimens and lantern slides depicting the progress of the disease since its discovery and the progress made in the study of the disease in animals and in man, incidence, distribution, etiology, pathology, diagnostic methods and salient features, treatment and particularly the relationship between the disease in domestic animals and in man.

UNITED STATES PUBLIC HEALTH SERVICE, Washington, D. C. *Undulant fever* Exhibit of charts and drawings dealing with the etiology, diagnosis, prevention and treatment of undulant fever.

W. J. McCONNELL and A. J. LANZA, Metropolitan Life Insurance Company, New York. *Diseases of the lungs caused by inhalation of dusts* Exhibit showing various harmful dusts used in industry, with roentgenograms of their effects on the lungs, together with a demonstration of methods of determining hazardous dusts in industry.

HENRY FIELD SMYTH and HENRY FIELD SMYTH JR., Laboratory of Hygiene University of Pennsylvania School of Medicine, Philadelphia. *Safe practices in industrial use of carbon tetrachloride* Exhibit of data and material gathered on experimental animals exposed to controlled concentrations of carbon tetrachloride vapors: measurements of vapor concentrations in several plants using or manufacturing the material, physical examinations of a number of workers exposed in industry to the material, photomicrographs of significant animal tissue, such as liver, kidney, sciatic nerve and ocular muscle.

LOUIS I. DUBLIN, Metropolitan Life Insurance Company, New York. *Public health aspects of cardiovascular-renal conditions* Exhibit of charts showing geographic variation in mortality from these conditions, trend of mortality from 1911 to 1935 by age groups, differential mortality by age and sex, mortality of white and colored persons compared, chances of eventually dying from these conditions, incidence of cardiovascular-renal conditions compared with other causes of death, proportion of all deaths caused by cardiovascular-renal conditions, analysis of cardiovascular-renal conditions according to specific organs affected, heart, kidneys, arteries, and other organs.

WILLIAM F. SNOW and WALTER CLARK, American Social Hygiene Association and New York City Department of Health, New York. *Recent advances in the attack on syphilis and gonococcal infection* Exhibit of motion pictures, lantern slides, graphs and epidemiologic case studies, data on state and local regulations and programs, requirements for applying the United States Public Health Service recommendations for a venereal disease control program, and material illustrating the physician's part in these programs.

### Section on Urology

WALTMAN WALTERS, HUGH CABOT, VIRGIL S. COUNSELLER and JAMES T. PRIESTLEY, Mayo Foundation, Rochester, Minn. *Successful methods in the surgical treatment of hypospadias and ectrophy of the bladder* Exhibit of illustrations showing results in the treatment of various types of hypospadias obtained by the operations of Bucknall, Ombredanne and Thiersch, transparencies of patients with ectrophy of the bladder before and after surgical treatment of ureteral transplantation to the colon and cystectomy, motion pictures showing technique of operations for hypospadias and ureteral transplantation.

OSWALD S. LOWSLEY, Department of Urology, the James Buchanan Brady Foundation, New York Hospital, New York. *Kidney operations* Exhibit of motion pictures, photographs and specimens of kidney operations, such as nephrostomy, nephropexy, heminephrectomy and repair of kidney rupture.

CARCINOMA REGISTRY COMMITTEE OF THE AMERICAN UROLOGICAL ASSOCIATION, Army Medical Museum, Washington, D. C. *Five year end results in bladder tumors* Exhibit of tables and charts showing five year end results in cases registered in the Bladder Tumor Registry of the American Urological Association, charts showing correlation of end result with size and grade of tumor and with treatment, photomicrographs illustrating typical tumors of varying grade with results obtained.

CLINTON K. SMITH and A. LLOYD STOCKWELL, Children's Mercy Hospital, Kansas City, Mo. *Enuresis* Exhibit of drawings, diagrams and charts demonstrating normal bladder physiology, diagnostic methods, clinical types, clinical results, and general summary of data.

GERSHON J. THOMPSON, Mayo Clinic, Rochester, Minn. *Transurethral surgery* Exhibit of photographs, wax models and charts portraying the technique involved in the operative treatment of patients suffering with vesical neoplasms, vesical calculi, ureteral calculi, vesical neck obstructions caused by benign and malignant prostatic enlargements, congenital deformities, contractures and other conditions.

FREDERICK LIEBERTHAL, Department of Genito Urinary Surgery, Northwestern University Medical School, Chicago. *Renal and ureteral stone* Exhibit of water color sketches, roentgenograms and charts selected from several hundred cases of renal and ureteral stone showing the various forms of the latter and the pathologic changes produced by them in the various portions of the kidney and its capsules, emphasis is placed on an appreciation of detailed pathologic data from a clinical standpoint, especially as regards diagnosis and treatment and the relation of these pathologic changes to operative technique.

### Section on Orthopedic Surgery

CHARLES E. SEVIER, ATHA THOMAS and GEORGE K. COTTON, University of Colorado School of Medicine, Denver. *Internal derangements of the knee joint* Exhibit of drawings, roentgenograms and anatomic and pathologic specimens, demonstrating the anatomy and physiology of the knee joint, also etiology and pathology of the more common types of intrinsic derangements, surgical procedures demonstrated by wax models and illustrations.

H. WINNETT ORR, Lincoln, Neb. *The use of skeletal traction with fixation in plaster-of-paris casts in fractures, compound fractures, joint injuries and leg lengthening operations* Exhibit of models in plaster and color and roentgenograms of diagnostic and end results, short case abstracts for some illustrative cases. Demonstration also to emphasize certain points with reference to the prevention and control of infection in the wound treatment. A collection of historical books in the treatment of fractures.

CHARLES MURRAY GRATZ, New York Post Graduate Hospital, Columbia University and City Hospital, New York. *Bio mechanics* Exhibit of photographs showing adhesions in the fascial planes of the body, particularly in relation to the sciatic nerve, photomicrographs of the fibers of the fascial planes and their covering, biomechanical tests of the fibers and the results of extensive research work summarized, also application to fascial transplantation noted, roentgenograms showing the normal distribution of air in the fascial spaces contrasted with roentgenograms showing arthritic and sciatic patients, histologic, biomechanical and clinical data presented to substantiate the belief that adhesions in the fascial spaces interfere with the functional mechanics of the soft tissues, particularly nerves, and may be responsible in certain cases for the production of pain.

ALBERT B. FERGUSON and FREDERICK L. LIEBOLT, New York Orthopedic Hospital, New York. *Lateral roentgenography of the femoral neck* Exhibit of a new film holder for readily obtaining the lateral view together with illustrations of the application of the method in orthopedic conditions, such as fracture epiphysiolysis, coxa plana, arthritis, tuberculosis, arthroplasty and congenital dislocation.

J. E. M. THOMSON and C. FRED FERCIOT, Lincoln, Neb. *Beaded Kirschner wire in the fixation of bone fragments* Exhibit of roentgenograms and illustrations portraying the technique of applying beaded Kirschner wires for the reduction and immobilization of certain fractures, such as oblique fractures of long bones and comminuted fractures in which there is a large loose fragment or fragments, and for use in immobilizing fragments after bone shortening operations.

LAURENCE JONES, Menorah Hospital, Kansas City, Mo. *Lateral roentgenography of the neck of the femur and its clinical application to the treatment of intracapsular fractures of the neck of the femur* Exhibit dealing with the problems involved in the taking of lateral roentgenograms of the neck of the femur, methods used in the past and difficulties associated with them, a new technique consisting of a different position and a specially

designed curved cassette with incorporated radiographic filter clinical examples, the application of the method to bring about improved reduction

WILLIS C CAMPBELL, J S SPEED JOSEPH I MITCHELL and J F HAMILTON, Dr Willis C Campbell Clinic, Memphis *Bone tumors* Exhibit of photographs of specimens photomicrographs, roentgenograms and case histories of various cases showing bone tumors

EARL D MCBRIDE McBride Clinic Oklahoma City *The conservative operation for bunions* Exhibit of motion pictures and of plaster and anatomic models demonstrating the technic and results in the conservative operation for bunions

ROBERT L PRESTON and MARJORIE B PATTERSON New York *An experimental study of acute staphylococcal suppurative arthritis* Exhibit of pictures, pathologic specimens and charts illustrating experimental study of various pathologic joint and systemic changes that occur during the course of disease in cases treated by the various methods now in use, comparison of the effectiveness of these methods of treatment in cases of infection by strains of staphylococci of widely varying pathogenicity, criteria for selecting the preferable method of treatment for a given clinical case

W EUGENE WOLCOTT, Des Moines Iowa *Circulation in the head and neck of the femur* Exhibit of transparencies made from films of the femoral heads injected with opaque material demonstrating the circulation entering the head of the femur through the ligamentum teres the circulation entering the neck and ultimately the head of the femur by way of the posterior superior and inferior visceral capsular arteries and the anastomosis between these vessels anatomic specimens demonstrating dissected hip joints

FRED H ALBEE New York *Recent advances in the treatment of fractures of the hip* Exhibit of roentgenograms showing end results of cases, diagrams and anatomic models showing the methods used in securing active stabilization of the hip and union in fracture of the neck of the femur with special emphasis placed on the treatment of those cases in which aseptic necrosis of the head occurs

Motion Picture Program Motion pictures dealing with orthopedic surgery will be run on a regular schedule in a space adjoining the exhibits of the section

#### Section on Gastro-Enterology and Proctology

HARRY SHAY, JACOB GERSHON-COHEN and SAMUEL S FELS, Philadelphia *Experimental studies in gastric physiology in man* Exhibit of serial roentgenograms showing pyloric function as controlled locally by duodenum and upper small intestine as modified by gastric secretory response as a test of Cannon's theory, as controlled by extrinsic factors its reciprocal behavior with the duodenum, its substitution in the resected stomach its functional relation to antrum and duodenum cap its quantitative response to duodenal stimulation its action with solid and liquid meals, its control by regional intestinal stimulation, also gastric emptying after gastro enterostomy

A C SCOTT SR M W SHERWOOD and G V BRINDLEY Scott and White Clinic, Temple Texas *Cancer of the rectum* Exhibit of moulages, charts and pictures showing development of cancer from benign to malignant lesions

RUDOLF SCHINDLER MARIE ORTMAYER and JOHN F RENSHAW University of Chicago Chicago *Chronic gastritis* Exhibit of metal tubes, containing gastroscopic pictures illuminating box containing lantern slides roentgenograms and gastrophotographs, charts, different types of flexible gastroscopies and books

E L EGGLESTON and B C WHYTE Battle Creek Sanitarium, Battle Creek Mich *Behavior of gastric intestinal tract under conditions of autonomic imbalance* Exhibit of photographic reproductions of serial gastro intestinal films illustrating types of behavior under different degrees of imbalance charts showing signs symptoms and physical observations

DAVID J SANDWEISS Detroit *Comparative value of dietetic and parenteral treatment of peptic ulcer* Exhibit of charts showing treatment with histidine hydrochloride synodal vaccine and distilled water injections, oral administration of silicon dioxide (sand) and diet alkali regimen charts showing comparative end results

J DONALD MILLIGAN, Pelton Clinic of Elgin, Elgin, Ill *Diagnosis and management of upper gastro-intestinal problems* Exhibit of gastric ulcer problems, gastric cancer problems, duodenal ulcer problems, small bowel obstruction problems, also diagnosis and differential diagnosis of each of these diseases with history and physical laboratory and roentgen studies

C W MAYO and E G WAKEFIELD, Mayo Clinic, Rochester, Minn *Disseminated polyposis of the colon, with a new combined surgical procedure for treatment of selected cases* Exhibit showing a familial review of a number of cases with polyposis, clinical and pathologic follow up and surgical technic in handling such cases

HENRY A RAFSKY, Lenox Hill Hospital, New York *The clinical significance of pathologic changes in biliary tract disease* Exhibit of charts illustrating the carbohydrate tolerance studied in a series of patients with biliary tract disease and post-cholecystectomy sequelae data illustrating that cholecystectomy in many instances resulted in marked improvement in the carbohydrate tolerance, charts showing various types of blood sugar curves and case reports giving clinical interpretation

CLAUDE C TUCKER and C ALEXANDER HELLWIG St Francis Hospital Wichita, Kan *Etiology and histology of pruritus ani* Exhibit of photographs and photomicrographs showing the different stages of pruritus ani and inflammatory changes in the anal canal found in cases of pruritus ani, demonstration of presence of nerve corpuscles explaining the extreme sensitivity of the anal papillae

WARREN T VAUGHAN, Richmond, Va *Food allergy* Exhibit of posters graphs, drawings and photographs outlining a comprehensive routine for study of food allergy skin tests, biologic food groups, leukopenic index, food diary, echelon dietary regimen, relative importance and reliability of these, therapeutic program and results

HORACE W SOPER St Louis *Special types of therapy in gastro-enterology* Exhibit of charts, roentgenograms, specimens and instruments dealing with special types of therapy employed in gastro enterology, including ulcerative colitis rectal diathermy, amebic dysentery, biliary drainage and cardiospasm

#### Section on Radiology

GEORGE LEVENE and HENRY H LERNER Robert Dawson Evans Memorial for Clinical Research and Preventive Medicine, Massachusetts Memorial Hospitals, Boston *Roentgenoscopic appearance of the heart* Exhibit of moving mechanical models that reproduce the appearance of the heart as seen under the fluoroscope including normal conditions sinus arrhythmia, extrasystoles heart block, auricular fibrillation, thromboembolism coronary disease, aortic stenosis aortic insufficiency and tricuspid insufficiency electrocardiograms of these conditions and technic of fluoroscopic study

HAROLD G F EDWARDS Shreveport La *Radium and roentgen rays in the treatment of cancer* Exhibit of transparent tinted photographs of malignant tumors before treatment, photomicrographs of tumor and photographs showing radium in situ and the end results secured by such treatment, when cases have been treated with the roentgen ray, the skin reaction is shown

WENDELL G SCOTT and SHERWOOD MOORE Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine, St Louis *Clinical and physiologic value of kymography in diseases of the heart and chest* Exhibit of roentgenograms, charts, photographs of apparatus and short case reports dealing with the clinical and physiologic information gained from roentgenokymograms in diseases of the heart and chest kymograms in aortic insufficiency, aortic stenosis hypertrophic cardiomyopathy aneurysms of ascending arch of the aorta pleuropericardial adhesions myxedema and adhesive pericarditis kymograms of the diaphragm showing the movements in atelectasis pneumonia asthma, emphysema hiccuping eructation, coughing and with adhesions, kymoscope for demonstrating the movements recorded on the kymograms

HARRY H BOWING and ROBERT E FRICKE Mayo Clinic Rochester Minn *The treatment of rectal carcinoma with radium* Exhibit of drawings and charts showing the location and types of lesions encountered, location and method of maintaining the radium applicators in position for the required treatment time the age incidence the location of the lesions the grade of pathologic change encountered and the results obtained

DAVID S DANN, Menorah Hospital Cancer Clinic, Kansas City, Mo *A practical guide to therapy in cancer* Exhibit of graphic charts of the body divided in the sagittal and coronal planes with the treatment of choice, surgery, irradiation or both, for each anatomic location of the tumor, indicated in colors, photographs illustrating the accomplishments of treatments in various types of cancer

WILLBUR BAILEY, Department of Radiology, University of Southern California School of Medicine, Los Angeles *Anomalies and fractures of the vertebral articular processes* Exhibit of a series of such lesions of the vertebral articular processes showing the anomalous centers of ossification which are occasionally seen opposite the tips of the inferior articular processes of the lumbar vertebrae Partial fusion or complete lack of fusion of such ossicles may be confused with fracture Isolated fractures of the articular processes may occur in the same region, but from the history and the roentgen appearance a differential diagnosis can nearly always be made

J C KRAVING, O A BRINLS and HARRY L WITZ, City of Detroit Receiving Hospital, Detroit *Primary carcinoma of the lung* Exhibit of roentgenograms of cases of primary carcinoma of the lung, with resume of clinical history and other observations, together with photomicrographs and gross pathology, demonstrating the pathology with particular emphasis on cell type

E A MERRITT, EDGAR M MCPHEA and R RHEFT RATHBON, Warwick Clinic, Garfield and Emergency Hospitals, Washington, D C *The application of the Contard principles of radiation therapy in malignancy* Exhibit of colored lantern slides showing the intense blistering skin reactions as well as the primary lesions before and after treatment of typical cases of carcinoma of the breast stomach, colon, rectum and cervix, bladder and skin, as well as a group of miscellaneous malignant conditions

J M MARTIN and CHARLES L MARTIN, Baylor University Hospital, Dallas, Texas *Radiation therapy in carcinoma of the lower lip, mouth, tongue, larynx and pharynx* Exhibit of enlarged photographs of actual cases of cancer before, during and after treatment accompanied by charts and drawings, models of cancer lesions accompanied by photographs, photomicrographs, drawings and legends, photographs illustrating the various steps in cancer therapy

H O MAHONEY and BARRY J ANSON, Northwestern University Medical School, Chicago *Radiographic study of anatomic sections* Exhibit of a representative selection of roentgenograms and corresponding photographs of anatomic sections, coronal, transverse and sagittal, so arranged and labeled as to show the advantages which radiography provides in the study of anatomy, revealing of anatomic structure not readily shown by usual methods of study, recording of macroscopic differences among organs, course of the fascicles of muscles and the arrangement of the trabeculae of bone, making possible a complete and thorough study of anatomic sections without disturbing the tissue or destroying the sections

#### Group Exhibit, University of Kansas School of Medicine

RALPH H MAJOR, Department of Medicine *Insulin absorption* Exhibit of charts showing observations on insulin absorption

EDWARD H HASHINGER, Department of Medicine *Influence of hypophysis on blood platelets* Exhibit of charts showing influence of hypophysis on blood platelets

GRAHAM ASIFR, Department of Medicine *Simultaneous phonocardiograms and electrocardiograms* Exhibit of tracings and charts showing simultaneous phonocardiograms and electrocardiograms

LOGAN CLENDENING, Department of Medicine *History of medicine* Exhibit of American books important in the history of medicine

THOMAS G ORR, Department of Surgery *Breast amputation* Exhibit of drawings illustrating technic for breast amputation

NELSE F OCKFRELAD and HJALMAR E CARLSON, Department of Surgery *Effect of morphine on the human ureters* Exhibit of tracings showing the effect of morphine on the human ureters

E C PADGETT, Department of Surgery *Reconstruction of ears* Exhibit of photographs, diagrams and wax models showing total reconstruction of ears

H C TRACY, Department of Anatomy *Anatomic models* Exhibit of anatomic models of brain stem and heart embryos

L A CAIKINS, Department of Obstetrics *Size of placenta* Exhibit of charts showing size of placenta with causes and effects of variations

FRANK C NEFF, G V HERRMAN and ROBERT FREDEEN, Department of Pediatrics *Transfusion of infants* Exhibit of apparatus and charts describing a method of transfusions of infants

SAM ROBERTS, Department of Otorhinolaryngology *The pyriform sinus* Exhibit showing a new surgical approach to the mediastinum through the pyriform sinus

O J DIXON, Department of Otorhinolaryngology *Mastoidectomy* Exhibit of drawings, roentgenograms and photographs showing a new type of mastoidectomy wound closure

O O STOLAND and A M GINSBERG, Department of Physiology *Studies of coronary circulation* Exhibit of charts and graphs describing technic and experimental work on coronary circulation

F C HRIWIG, Department of Pathology *The hepatorenal syndrome* Exhibit of charts and photomicrographs showing clinical and pathologic studies of the hepatorenal syndrome

EMSLY T JOHNSON, Department of Pathology *Liver damage due to drugs* Exhibit of gross specimens and photomicrographs of experimental work and results of necropsy in liver damage due to drugs

#### SYMPOSIUM ON TRAFFIC ACCIDENTS

This group of exhibits is intended to give the physician practical information in the treatment of traffic accidents

SPECIAL EXHIBIT *Emergency treatment for transportation of fractures of the lower extremity* Exhibit presented by Special Exhibit Committee on Fractures

HARRY E MOCK, Northwestern University School of Medicine, and St Luke's Hospital, Chicago *Skull fractures* Exhibit of charts and photographs illustrating prevention, etiology, pathology and management of skull fracture cases, stressing the part automobile accidents are playing in skull fractures and preventive measures which should be adopted during the first twenty-four hours

SAUEL McLANAHAN, Baltimore *Automobile door handle injuries* Exhibit of roentgenograms, photographs and case histories, depicting a number of unusual instances of serious injury caused by the projecting type of door handle currently used on automobiles, a collection of newspaper clippings describing such injuries to man and beast, illustrations of dangerous types of door handles, and of improved types which have been suggested

CLAIRE L STRAITH and WILLIAM A LANCE, Detroit *Plastic surgery* Exhibit of photographs showing technic and results in plastic surgery Special emphasis is placed on the treatment of crushing facial injuries such as those so often encountered by surgeons in treating victims of motor car accidents, apparatus will be shown which will hold facial bone fragments and reshape crushed faces

ALBERT L LEMOINE, Kansas City, Mo *A motion picture "Safety First"*

#### EDUCATIONAL CLASSIFICATION

##### Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than the individuals and which are intended to show progress in the particular activities with which those institutions deal

These exhibits are not open to medal awards, but a special certificate of merit is presented to the best exhibit in this classification

AMERICAN HEART ASSOCIATION, New York *A group of three exhibits on studies of the revved human hearts, consisting of motion pictures and charts, the pathology of rheumatic fever consisting of charts and specimens, the treatment of congestive heart failure, are shown by lantern slides*

HEALTH CONSERVATION ASSOCIATION, Kansas City, Mo. Exhibit of large diagram of the organization showing the unification and coordination of several local volunteer health educational agencies, illustrations of program of the association

UNITED STATES PHARMACOPEIA *The Eleventh Revision of the United States Pharmacopoeia* Exhibit of pharmacopoeial preparations and chemicals and a demonstration of the use of these in prescription practice

AMERICAN PHARMACEUTICAL ASSOCIATION, Washington D C *The Notional Formulary* Exhibit of new and valuable products of the Sixth Edition of the National Formulary

COMMITTEE ON DEAFNESS PREVENTION AND AMELIORATION, American Academy of Ophthalmology and Otolaryngology *Deafness prevention and amelioration* Exhibit of instruments, charts, posters and diagrams illustrating methods of detecting and determining amount of hearing loss by modern methods, a working model of acoustically treated testing room to make possible accuracy in diagnosing disturbances of hearing audiometers and hearing aids, their use in the field of deafness prevention and amelioration lantern slides and films illustrating educational talks in this field, available literature on subject

AMERICAN SOCIETY FOR THE HARD OF HEARING Washington, D C Exhibit of posters charts, maps and distribution of pamphlets on the needs of the hard of hearing from an educational, vocational and economic standpoint

AMERICAN SOCIETY FOR THE CONTROL OF CANCER New York *Constitution and cancer* Exhibit of charts and other material showing the constitutional factors in production of cancer in animals, constitutional factors showing the incidence of cancer in different strains, production of cancer by carcinogenic agents in relation to its constitutional condition subject of transplantation and its physiologic factors

NATIONAL CONFERENCE ON NOMENCLATURE OF DISEASE, New York *National Conference on Nomenclature of Disease* Exhibit of placards explaining the origin and constitution of the National Conference on Nomenclature of Disease the design of the nosologic classification a record room set up according to various plans, together with placards showing cost of installation, graphic illustrations of the simplicity of the system and a spot map showing distribution of the Standard Classified Nomenclature of Disease

MISSOURI STATE COMMITTEE ON MATERNAL WELFARE St Joseph, Mo *Maternal welfare* Exhibit of charts maps and diagrams of maternal and neonatal mortality throughout the United States, a clock or sand glass calling attention to the fact that each time the minute hand circles the clock so many mothers and infants die specimens of one to nine months fetuses, slips to sign for literature

NATIONAL TUBERCULOSIS ASSOCIATION New York *The tuberculin test* Exhibit of apparatus used in making the tuberculin test, panels and graphs showing how test is made reproductions of reactions statistical graphs and other material illustrating the significance of the tuberculin test

AERO MEDICAL ASSOCIATION *Scientific apparatus used in determining fitness of airplane pilots* Exhibit of apparatus for testing coordination, mental reflexes, fatigue and other phenomena

ADVISORY BOARD FOR MEDICAL SPECIALTIES Exhibit of charts graphs and literature describing the work of the Advisory Board for Medical Specialties and its member organizations

AMERICAN ASSOCIATION OF MEDICAL SOCIAL WORKERS, Chicago Exhibit of charts and reports of studies on some social factors in certain diagnostic groups function of the social worker in relation to illness organization of social service departments in hospitals

NATIONAL BOARD OF MEDICAL EXAMINERS, Philadelphia Exhibit of charts describing the work and progress of the National Board of Medical Examiners

ASSOCIATION OF AMERICAN MEDICAL COLLEGES Chicago *Medical Education* Exhibit of charts giving information on the various activities of this association, such as accomplishments of students in medical schools correlation of work in medical schools with work done in art colleges, analysis of entrance credentials and study of applicants for admission to medical schools

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION, New York *Occupational therapy* Exhibit of photographs, diagrams, charts, case abstracts and other means of demonstrating graphically a few of the methods of aiding the recovery of the sick by means of occupations of various kinds

AMERICAN PHYSIOTHERAPY ASSOCIATION *Analysis of the exercise treatment of the foot* Exhibit showing significant points in the kinesiology of the foot analysis of foot exercises, contraindications for the use of certain foot exercises, demonstration of foot exercises

NEW YORK STATE INSTITUTE FOR THE STUDY OF MALIGNANT DISEASES, Buffalo *Cancer—what is being done about it* Exhibit of colored transparencies showing various types of cancer, accompanied by short histories, description of lesions, pathology, diagnosis, treatment and results, doll exhibit showing the treatment of cancer by surgery, roentgen ray and radium, and a 45 Gm radium bomb (pack) made to scale, a miniature x-ray machine and miniature surgery exhibit, a radon pump demonstrating the pumping process, various forms in which radium and radon are used gold radon seeds glass bulbs, needles, plaques tubes, cards with cancer hints for the physician to apply in caring for his patients, wax models of cancer found in various parts of the body

### American Medical Association

The exhibits from the headquarters group of the American Medical Association will be found in various parts of the hall These exhibits are not open to awards

BUREAU OF MEDICAL ECONOMICS Exhibit of charts showing distribution of physicians, university and college student health service

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS Exhibit of graphs, maps, charts, pictures and mechanical apparatus dealing with the resurvey of medical education, training of interns and resident physicians, certification of specialists, survey of schools of occupational therapy, physical therapy and laboratory technique the hospital register the special survey of tuberculosis hospitals, and other activities of the Council on Medical Education and Hospitals

COUNCIL ON PHYSICAL THERAPY Exhibit consists of four sections 1 Visual demonstration with a plethysmograph showing changes in volume of tissue fluids in fingers after application of heat 2 Visual demonstration of some fundamental concepts of short wave diathermy Apparatus constructed by secretary of the Council 3 Demonstration by means of model bearing on the importance of posture in relation to disease 4 Charts dealing with the Council's educational program

BUREAU OF HEALTH AND PUBLIC INSTRUCTION Exhibit of charts, maps and literature showing the work of the Bureau and the relation of public health to the Social Security Act

### AWARDS

There will be two classes of awards, consisting each of (a) a gold medal, (b) a silver medal, (c) a bronze medal and (d) three certificates of merit

[NOTE—The special (subsidized) exhibits (diabetes and fractures) and the exhibits of the headquarters of the American Medical Association are not open to awards]

#### CLASS I

Awards in class I are made for exhibits of individual investigations, which are judged on basis of originality and excellence of presentation

#### CLASS II

Awards in class II are made for exhibits that do not exemplify purely experimental studies, which are judged on basis of the excellence of correlating facts and excellence of presentation

Medals are awarded only to individuals A special certificate of merit will be awarded to the best educational exhibit in the Educational Classification (this includes exhibits by national organizations)

The Committee on Awards will be composed of five persons It will make the decisions on Wednesday, May 13

The names of the members of the Committee on Awards will not be available until after the decisions have been published

# THE TECHNICAL ★ EXPOSITION ★

## APPARATUS AND INSTRUMENTS

### Short Wave and Elliott Machines

While the A. S. Aloe Company will display a complete line of instruments and equipment for the doctor and hospital, special interest will be centered in demonstration of the Aloe Short Wave Diathermy, the Elliott Treatment Machine and the new Magnuson Counter Rotary Bone Saw. A special discount on rustless steel instruments will be offered during the convention. A new suite of American Walnut furniture will be featured. Booths 20, 21 and 82.

### A Rib-Back Blade

The Bard-Parker Company will demonstrate in Booths 32 and 33 the outstanding features of the Rib-Back surgical blade which

incorporates new standards of sharpness, rigidity and strength and eliminates operating interruptions due to glove cutting and blade rejects.

### Splint Kit for Doctors' Cars

The Frank S. Betz Company will have on exhibit in Booth 141 a new and complete all steel office group, a complete display of surgical instruments, the latest make and design short wave diathermy and majestic portable electro-surgical unit, physicians' genuine leather bags and an emergency first aid splint kit as approved by Dr. Kellogg Speed for physicians' cars and ambulances.

(Continued on next page)

WHAT are the new improvements in products and services needed by the physician in the practice of medicine? What forward strides have been made in research by manufacturers? How do their technical advances help to serve the doctor better?

THIS year the Technical Exhibits at the American Medical Association Convention will aid in answering these questions. They will permit the visiting physician to come into personal contact with the products and representatives of more than 200 leading firms—manufacturers of pharmaceuticals and biologicals, publishers of medical books, makers of instruments, apparatus and electrical equipment, as well as dietetic products, and many other highly specialized articles and services.

ALMOST invariably, one will find well qualified representatives in each booth eager to discuss subjects of mutual interest. At many exhibits will be scientific investigators and skilled technicians who conducted the research on which the exhibit is based.

THE Exposition will be open from 8:30 A. M. to 6:00 P. M. each day, closing Friday at noon. These hours, together with the close proximity of the Technical Exposition to the Scientific Exhibit and all meeting places, will make it unusually convenient for the physician to take full advantage of the stimulating and educational opportunities offered by the exhibits.

— WILL C. BRAUN, Superintendent of Exhibits

### New Improved A S R Surgeon's Blade

After months of experiment, during which time prominent medical authorities were constantly consulted this Keener more uniform Surgeon's Blade was developed. It fits all standard surgical handles old and new.

A complete line of these blades—nine types in all—will be exhibited in booth 167. Samples for test purposes will be supplied.

### A New Kind of Surgical Knife

Proper steel heat treating and good sharpening processes is relieved in the Beaver knife will be explained by Rudolph Beaver, Inc. Waltham Mass. in Booth 231. Beaver blades are not water blades, but are stronger and thicker blades and the mechanism is very simple. All the various blade shapes to fit the different stainless steel handles will be shown.

### New Clinical Camera

A new clinical camera will be displayed by the Burton Manufacturing Company at Booth 261. The camera is specifically designed for the exacting work of intra and extra cavity photography and is already widely used. It especially appeals to the practitioner because it is almost foolproof and may be operated by any one without previous photographic experience.

### Castle Lights and Sterilizers

A brand new light for physicians' use in examination, treatment and minor operative work will be shown at the Castle Booths 102 and 129. It is radically new in design and though inexpensive gives a cool color corrected light which almost equals the fine Spot Lights and Major Lights which Castle makes for surgeries. A big line of Major Lights and "Full-Automatic Cast in Bronze Sterilizers will also be displayed in profusion.

### Cayo Power Instruments

In booth 218 the Cayo Brothers will demonstrate their bone instruments and explain the technique they use in various operations. Among the features worthy of note will be the Cayo Method of entering the surgical field without danger of contamination.

### Passive Vascular Exerciser

The Cincinnati Scientific Company will demonstrate the Passive Vascular Exerciser Unit for stimulating the development of collateral arterial circulation in the extremities of patients with organic arterial diseases. An interesting demonstration will be made at their booth No. 256 of the effect of the rhythmic alternation of environmental pressure upon an artificial circulation.

### Improved Respirators and Oxygen Tents

At Booth 35 Warren E. Collins, Inc. will demonstrate the latest developments in Adult and Infant Drinker Respirators. The Benedict-Roth Metabolism

Apparatus has many improvements which include direct vital capacity readings. The new Collins Oxygen Tent with added improvements for simplicity and economy will also be on display. Courteous technicians will give demonstrations and answer all questions.

### Sample Surgical Blades

Call at Booth 199 for your free sample of the better Surgeons' detachable blade—Crescent Products of the Crescent Mfg. Co. of Fremont Ohio. Representatives will tell you why Crescent blades are preferred by Surgeons and how over two thousand hospitals are now saving 20 to 25% by their purchases of Crescent blades.

### Sutures for Special Purposes

Davis & Geck, Inc. will show their complete line of sterile surgical sutures with atraumatic needles suited for tonsil, thyroid, obstetrical, circumcision, plastic eye, ureteral and renal work—also ribbon gut and their new line of dental sutures. See the films from their Library of Surgical Motion Pictures to which many new subjects have been added. Booth 37.

### New Fracture Equipment

Aluminum X-Ray Splints Hyperextension Frames and other fracture equipment will be exhibited in booth 84 by the DePuy Manufacturing Company. Radiographers and Fracture Surgeons will find this exhibit very interesting.

Trained men will be in attendance to explain the advantages of new equipment.

### Nasal Guard for Atomizers

The DeVilbiss Company, manufacturers of medicinal atomizers, have reserved Booths 113 and 114 for a complete showing of their line of atomizers and vaporizers for both home and professional use. A prominent feature of the DeVilbiss Exhibit will be the recently developed DeVilbiss Nasal Guard which prevents any excess pressure in the nasal passages during prescribed self-treatment.

### Acousticon Hearing Aids

The Dictograph Products Company, Inc. will give practical demonstrations of the new Amplified Air and Bone Conduction Acousticon hearing aids and explain the special service available for patients. Also in Booth 165 will be a display of the Telematic Jr. modern intracommunication system for the professional man's office, consultation room and any other part of the building desired.

### The New Gomco Centrifuge

In Booth 211 will be shown the new Gomco Centrifuge which incorporates a number of distinctive features. The famous line of Circumcision Clamps will also be shown and any questions pertaining to the technique required will be answered by capable persons in charge.

### Improved Respirators

In Booth 210 a new respirator collar arrangement which makes it possible for one person to put a patient into a respirator without assistance will be demonstrated by J. H. Emerson. This will be shown in connection with interesting demonstrations of the Emerson Respirator. Representatives skilled in the problems of artificial respiration will be present. Other hospital and research equipment will be displayed.

### Will Display Gas Machines

The McKesson Appliance Company invites you to visit their booths Nos. 216-217. Here they will have on display the latest advances in anesthesia metabolism, oxygen therapy and allied equipment.

### To Show New Apparatus

In addition to their regular line of kymometers and oxygen therapy equipment the Heidbrink Company will display for the first time this year their new Cabinet Model, a marvel of convenience and efficiency. Visitors interested in the latest developments in gas anesthesia or oxygen therapy equipment will do well to call at Booth 203 and obtain a complete demonstration by competent representatives.

### Orthopedic Appliances

The W. E. Isle Company will display the latest prosthetic and orthopedic appliances in their booth, No. 209. The exhibit will feature the Isle Superior Artificial Limb with Natural Action, Sponge Rubber Foot, surgical supports and Adjustable Bradford Frame.

### New Pelton Sterilizer

In Booth 202 the Pelton & Crane Company will show a complete line of sterilizers, operating lights and fountain euspidors. A feature of this year's exhibit will be the new Pelton Tri-Plex Sterilizer which includes built-in instrument sterilizer, automatic autoclave and modern handsome cabinet.

### Late Model Operating Table

The remarkable performance of the Operay Multicolumn light with flexible swivel offset hanger will be demonstrated in combination with the extensive surgical conveniences of their new operating table in the Scanlan-Morris Company's exhibit booths 153 and 154. New electric sterilizers and representative items of their new line of surgical furniture and hospital equipment will also be displayed.

### Chevalier Jackson Instruments

The George P. Pilling exhibit will afford an opportunity to examine a modern complete showing of thoracic instruments.

many new brain and eye, ear nose and throat instruments, and, of course, the well-known Chevalier Jackson bronchoscopic instruments made by this firm. Their pneumothorax apparatus includes a wide choice of both hospital and portable types and accessories. Visit Booth 106.

### Improved Food Conveyors

At Booth 181 the Prometheus Electric Corporation will display a complete line of improved food conveyors sterilizing equipment and infra-red equipment with new patented 3 heat control. New model sterilizers with east bronze boilers, fully automatic heat control and other features will also be displayed and explained.

### Simplified Pivot Leg Splint

The J. R. Siebrandt Mfg Co will feature at their exhibit Booth 206, an improved Reduction Frame designed by Dr. R. A. Griswold of Louisville, Ky. While the frame assures accurate anatomic reduction and firm fixation, it is noted for its simplicity and adjustability. They will also show the Simplified Pivot Leg Splint, which is the original rocking leg splint equipped with scale traction and easy to apply.

### Surgical Apparatus

The J. Sklar Manufacturing Company, makers of surgical instruments and surgical apparatus, will exhibit in Booths 76 and 77. They will show their complete line of American Made Stainless Steel as well as pumps and special apparatus including Davidson's Pneumothorax Apparatus, Barks Automatic Direct Blood Transfuser, Dr. Printz's New Hospital Suction Unit, Tompkins Portable Rotary Compressor and other specialties of interest to physicians and surgeons.

### Suction and Pressure Apparatus

C. M. Sorensen Company will have on display, in Booth 150 several interesting models of combinations of Suction and Pressure Apparatus also allied accessories for tonsil irrigation, and Dr. Schullinger's new apparatus for displacement filling of nasal sinuses.

### Cast Cutter to Be Shown

The Cary Cast Cutter will be shown and demonstrated by Zimmer Manufacturing Company in Booth 143. This is a new hand cast cutter which needs only to be seen in use to be appreciated. A complete line of the modern fracture appliances will also be on display. All doctors are invited to this booth.

### Electromedical Apparatus

Progress in the design of apparatus for x-ray diagnosis and high voltage therapy may be seen in this year's exhibits of the General Electric X-Ray Corporation. From the modest requirements of average office practice up to the powerful equipment designed for the specialized x-ray department, the wide G. E. line offers a selection exactly

sued to your individual needs. The G-E Inductotherm and other physical therapy apparatus will also be shown. Booths 155, 156, 157 and 158.

## BOOKS

### New "Practitioners Library"

An outstanding feature of the D. Appleton-Century exhibit, Booth 52, will be their "Practitioners Library of Medicine and Surgery" now nearing completion under editorial supervision of Dr. George Blumer. There will also be on view the first of three volumes of their new "Postgraduate Surgery," Sir William Osler and Thomas McGraw's "Principles and Practice of Medicine" and the new edition of Milton J. Rosenau's "Preventive Medicine and Hygiene."

### Blakiston's Book Display

Space 109 will be occupied by P. Blakiston's Son & Co., Inc., who will exhibit the following books: East's "Medical Aspects of Crime," Halliburton & McDowall's "Physiology," Lawrence's "Diabetic Life," Osmond's "Laboratory Diagnosis," Piney & Wyard's "Atlas of Blood Diseases," Strecker & Ebaugh's "Clinical Psychiatry," Whitby & Britton's "Disorders of the Blood," Winton & Bryliss' "Physiology."

### "Cyclopedia" on Display

Convention visitors are cordially invited to stop at Booth 222 and examine the interesting new books which are being shown for the first time by I. A. Davis Company. The Cyclopedia of Medicine and Surgery, in twelve large volumes will be an outstanding feature of the exhibit.

### Lea & Febiger Medical Works

Lea & Febiger will exhibit some important new books and new editions at Booth 116. The new titles include Graham Singer Ballou's "Diseases of the Chest," Berglund & Medes on the Kidney, Hawes & Stone on Tuberculosis, and DeRivas' "Parasitology." New editions include Joslin's "Diabetes," Jelliffe & White's "Nervous Diseases," Boyd's "Pathology of Internal Diseases" and Stimson's "Contagious Diseases."

### To Feature Unusual Books

You can see these new books and new editions at the J. B. Lippincott Company's exhibit, Booths 79 and 80. Pfander & Schlossmann's "Diseases of Children," Pehani & Amreich's "Operative Gynecology," Kirschner & Ravdin's "Operative Surgery," McBride's "Disability Evaluation," Barborak's "Treatment by Diet," Sr. Gabriel's "Through the Patient's Eyes," Barker's "Treatment of the Commoner Diseases," Lisendath & Rolnick's "Urology," Anspach's "Gynecology," and the International Clinics' and "Annals of Surgery."

### "Textbook of Obstetrics"

The Macmillan Company will have on display at their booth, No. 96 new and outstanding books in many branches of medicine and surgery. One important work to be shown is Irving's "Textbook of Obstetrics," just published. Their representatives will be glad to give you information concerning this or any other of their books in which you may be interested. Proofs of several books now being printed will also be shown upon request.

## To Show Newer Publications

In Booth No. 7, the C. V. Mosby Company will feature their new publications released within the past year. Among the items to be shown are Taussig's "Abortion," Bray's "Synopsis of Clinical Laboratory Methods," Hunsel's "Allergy of the Nose and Paranasal Sinuses" and Sadler's "Theory and Practice of Psychiatry."

### From the Oxford Press

Visitors are invited to visit Booth 118 to review recent medical publications of the Oxford University Press. Among those to be shown are "Diagnosis and Treatment of the Heart," by Dr. Henry A. Christian, "Diagnosis and Treatment of Diseases of the Peripheral Arteries," by Dr. S. S. Samuels, and the Oxford "Loose Leaf Medicine."

### Shown for First Time

The union of the old house of William Wood and Company with the young house of Williams & Wilkins brings an excellent combined exhibit to Booth 86. Books shown for the first time include Beck's "Obstetrical Practice," Grollman's "The Adrenals," Himes' "Medical History of Contraception," Harrison's "Roentgenology," and Henry's "Psychopathology."

### A New "Parenteral Therapy"

Dutton and Lake's "Parenteral Therapy" covering general technic, hundreds of diseases, and over 700 drugs with which parenteral medication is concerned, may be inspected at Booth 80. Other new books to be shown by Charles C. Thomas include Landsteiner's "The Specificity of Serological Reactions," E. P. Sloan's "The Thyroid Surgery," Syndromes, Treatment, Percy Brown's "American Martyrs to Science Through the Roentgen Rays," and Kanner's "Child Psychiatry."

### Annals of Medical History

Paul B. Hoeber, Inc., Medical Department of Harper and Brothers, will display their entire line in Booth 83. Current numbers of the Annals of Medical History will be shown, together with copies of back numbers since 1917. Among recent monographs to be displayed are Riesman's "Story of Medicine in the Middle Ages," Warhass's "The Doctor and the Public Weir," "Diseases of the Liver, Gall Ducts & Pancreas," and Jacoby's "Physician, Pastor and Patient."

### "Surgery, Gynecology and Obstetrics"

A cordial invitation to visit Booth 180 is extended by the Surgical Publishing Company. Here you can inspect the "International Abstract of Surgery," a review and index of the world's current surgical literature, published as a part of "Surgery, Gynecology and Obstetrics." Also to be displayed is "The Joy of Living," an autobiography by the late Dr. Franklin H. Martin.

## DIAGNOSTIC APPARATUS

## For Showing Body Cavity Secrets

Among the interesting instruments made for throwing light into hidden cavities of the body by the American Cystoscope Makers, Inc. are the Wrapper Cystoscope, the Cutler Thoracoscope, the Ruddock Peritoneoscope and many others. These will be explained and demonstrated in booth 230 by competent representatives. Many of the instruments are of new development.

## Blood Pressure Specialists

Attendants at the booth of W. A. Baum Co. will be glad to give to visiting physicians whatever knowledge the company has accumulated out of its twenty years experience in the manufacturing of mercury-gravity sphygmomanometers. The newest cast duralumin Baummanometer will be shown and a copy of the U. S. Bureau of Standards booklet given free to visitors. Booth 136.

## Blood Chemistry Units

In booth 81 will be shown LaMotte Blood Chemistry Units for the physician. They will be in charge of chemists who can explain their simple operation in connection with blood and urine analysis. The improved Kline Slide Test for Syphilis will also be explained. Other standard diagnostic units will be included.

## Bausch &amp; Lomb Instruments

Scientific instruments for the medical profession and medical students will feature the exhibit of Bausch & Lomb Optical Company in Booth 62. These instruments will include the Model HA Physician's and Medical Student's Microscope, hemacytometers, colorimeters, clinical microtomes, hemoglobinometers, centrifuges, and accessory equipment for laboratory use.

## New Instruments for Old

In Booth 53 the Cameron Surgical Specialty Company will show the latest developments in electrically lighted diagnostic instruments. New diagnostic sets for Boston bags will be featured in a wide variety of prices. Also included will be the Tele-Vaginalite (Micro Colposcope) and the Cameron Cauterodyne. A representative will be glad to explain how it is possible to exchange present Cameron instruments for the more improved models.

## For Cardiac Diagnosis

Instruments to be found in the exhibition of The Cambridge Instrument Company, Inc. are the Handle Portable Electrocardiograph, the All-Electric Mobile Electrocardiograph, the Mobile Electrocardiograph-stethograph, the Stethograph Attachment, the Portable Stethograph and the Amplifying Stethoscope. A new development is their heart sound recording equipment. Booth 159.

## New Jones Motor-Basal

You may have your own metabolic rate taken by the Middlewest Instrument Company booth 178. See the demonstration of the new All-Electric Jones Motor-Basal, both hospital and portable models with inkless recording electric clock, waterless spirometer and direct reading technique.

## A \$550 Electrocardiograf

The operation and construction of the new low priced electrocardiograf called the Cardiette will be explained by the Sanborn Company in Booth 105. Technicians will also demonstrate the larger hospital size Electric-Portocardiograf and the latest Sanborn Motor Graphic Metabolism Tester Model E-I-S which features a spring-balanced oxygen bell and Stylograf chart records.

## To Show Optical Instruments

At the Spencer Lens Company Booth No. 49 there will be a complete line of scientific optical instruments of special interest to the medical group. It will include binocular microscopes featuring the convenient converging in-oculars, photomicrographic cameras with side focussing telescope microscopes and new microscope lamps for research work.

## New Instruments Featured

Recent developments in hand ophthalmoscopes and otoscopes will be shown at Booth 232. The Welch Allyn Company has added a number of features to these instruments some of which have never before been shown. Not only will their complete line of eye, ear, nose and throat instruments be on display but new rectal instruments, urethroscopes, vaginoscopes and cystoscopes.

## FOOD PRODUCTS

## For Pulping Baby's Food

Doctors will be interested in the new Junior Size Foley Food Mill which strains vegetables and fruits fine enough for infants quickly, easily and safely. It will be on exhibit in Booth 65 where representatives of the Foley Manufacturing Company will be pleased to explain its many uses not only for infants but for non-roughage diets.

## For Restricted Diets

Cellu Juice-Pak Fruit, consisting only of choice tree ripened fruit and added fruit juice of its own kind will be shown at Booth 198. The product is especially adaptable to quantitative diets of restricted carbohydrate value. The food values on the labels simplify calculations. Other special foods will be shown.

## Samples of Borchardt Products

At the Borchardt Malt Extract Company exhibit Booth 98 samples of the following products will be supplied upon request: Borchardt Malt Soup, Extract Malt with Cod Liver Oil, Malos (Malt Sugar) and Malt Extract Plain. Special information on recent bio-assays of Vitamins A, B and D will also be available.

## Gold Medal Foods on Display

General Mills, Inc. will display Limbo (wheat embryo) and also these nationally known Gold Medal Foods: Softasilk, Cake Flour, Bisquick, Wheaties and Kitchen-tested Flour Literature explaining the nutritive value of these wheat products together with suggestions for their use will be given free at Booth 236.

## Motion Picture Will Be Shown

A feature of the American Can Company exhibit will be a motion picture depicting the formation of the hermetic double seam on the tin container. Also at their booths 252 and 253 information will be available concerning those aspects of commercially canned foods which are of greatest interest to the medical profession. Literature on canned foods designed specifically for the physician's use will be on display.

## Sanka Coffee to Be Served

General Foods invite you to visit Booth 207 and drink a cup of Sanka Coffee. Then you'll know for yourself how rich it is in flavor and aroma, even though it's practically free from caffeine. Also on display at their booth you'll find D-7-erz, an attractive sugar-free gelatin dessert for patients on a low carbohydrate diet.

## Between-Meal Feeding

The Krim-Ko Company cordially invites visitors to call at Booth 197 for information about between-meal feeding satisfying children's candy hunger in a natural and nutritional way and getting more calcium and phosphorus into the diets of children who balk at drinking milk.

## Have a Cup of Coffee

Doctors are invited to visit the Kellogg Booth, No. 17, for a cup of refreshing Kaffee Hag Coffee. Bottle exhibits showing the stages in decaffeinating coffee are to be displayed and explanation will be given. Reports covering research on effects of caffeine and also on brew will be furnished upon request.

## Register for Nutritional Charts

The H. J. Heinz Company invites you to visit Booth 214 and see their display of tomato juice, breakfast cereals and strained

foods especially prepared for infant and convalescent feeding. Also they suggest that you register for the revised edition of their Nutritional Charts. It contains, along with vitamin mineral and food composition sections new ones on daily requirements and food allergy.

### Milk Irradiation

The Irradiated Evaporated Milk Institute in Booth 15 will show a novel display symbolizing in light color metal and photography the enrichment of evaporated milk with vitamin D by means of irradiation (Steenbock process). Literature will be available on infant feeding on the nutritive value and uses of the enriched milk and on the method and value of irradiation.

### See the Mechanical Cow

At the Nestle's Milk Products Inc Booth No 27 visitors will see the Nestle mechanical cow. She is a talented little lady who will blink her eyelids, wag her head, flick her tail and moo softly. Her markings represent the world-wide distribution of Nestle Products. Literature and samples of Lactogen Hylic and Nestle's Food will be available to all interested physicians.

### Pabulum

Mead Johnson & Company will show in Booths 36 and 37 the result of recent studies on the digestion and nutritive value of Pabulum. The physical characteristics of the product will be illustrated by photomicrographs and microprojector equipment and in-vitro enzymatic digestions will be performed showing how various starches digest when cooked by different methods. Charts will also visualize some of the nutritive values of Pabulum.

### Infant Feeding

Fitting the food to the baby, the correct approach to bottle feeding and other principles underlying the Mellin's Food method of milk modification will be discussed by well qualified representatives at Booth 91. Physicians are cordially invited to call.

### A Completely Modified Milk

The M & R Dietetic Laboratories will have in their display Similac, a completely modified milk for infants deprived of breast feeding. Representatives will be on hand to explain the value of the low curd tension of Similac as it applies to infant feeding and also the special cases in which it has proved beneficial. They will also explain the value of Spiruline as a mineral supplement. Booth 97.

### Palatable Products for Baby

Stokely Brothers and Company will exhibit their Strained Foods for babies in Booth 182. Their nine varieties include cereal, vegetable soup, spinach, carrots, peas, green beans, tomatoes, prunes and apricots—all packed in golden enamel lined

cans, and seasoned with salt or sugar under laboratory control—and all distinctly palatable. Visitors are invited to call and register.

### SMA and Smaco Products

The SMA Corporation will offer for your attention at Booth 57 the story of the significant resemblances of SMA to breast milk. The display will also include Smaco Carotene crystals, liquid, and capsules for providing concentrated vitamin A activity in the same form in which it occurs in the normal human diet.

### Learn About Vegex

The Vegex exhibit will show a study in tests for Sheiman B<sub>1</sub> units and B<sub>2</sub> (G) units, International B<sub>1</sub> units with B complex free test comparisons. Photostats from medical literature mentioning Vegex will be given. As usual the exhibit will demonstrate the palatability of Vegex with butter on bread, in broth, milk and tomato juice. Booth 71.

### To Serve Vitamin D Milk

The Vitex Laboratories will again serve Vitex Vitamin D Milk at Booths 240 and 241—all you can drink. Every quart of Vitex Vitamin D Milk contains 400 U.S.P. units of the cod liver oil Vitamin D.

### MISCELLANEOUS

#### Public Health and Laundering

The exhibit in Booth 215 will illustrate how the science of laundering fits into the public health program. It will show what the American Institute of Laundering has determined by accurate laboratory testing about the relative efficiency of home and commercial laundering processes. Fully informed attendants will be present to explain the exhibit and descriptive booklets will be available.

#### Better-Sight Desk

A visit to Booth 116 will show what a progressive school seat manufacturer has accomplished to protect the health of school children. You will see here what the American Seating Company has done to develop a new type of school seat that makes correct posture natural and comfortable and at the same time relieves children of the eyestrain usually associated with old type of school seating.

#### Aznove's Employment Service

An experienced representative will be on hand at Aznove's National Physicians Exchange Booth No 107. She will be glad to assist all employing officials interested in adding to, or making a change in their present personnel, whether it be a physician, nurse, dietitian, technician or other.

medical assistant. This service is free to employers. Also the representative will be glad to discuss the Aznove service with those seeking an appointment or desiring to make a change.

### Motion Picture Equipment

In Booth 194 Bell & Howell will display and demonstrate various types and sizes of Ilmo movie cameras, projectors and accessories showing models for every purse and purpose. Included will be the new Ilmo Straight 8 and Double 8 Cameras featuring the world's smallest practical movie cameras which use low cost 8 mm film.

### The Doctor and the Law

How medical liability insurance has kept pace with the science of medicine may be learned at Booth 25, where the Medical Protective Company, which specializes in this field, will be represented. Complete sets of the quarterly booklet "The Doctor and the Law," prepared by the Company's Law Department, will be available for examination. This publication represents an exclusive prophylactic and protective service by this Company to its clients.

### Medical Personnel

In Booth 3 M Burneice Larson will offer the facilities of the Medical Bureau which deals with problems of medical and nursing personnel. The records of physicians who have specialized men and women interested in assistantships, accredited graduate nurses and laboratory technicians and dietitians will be available to those interested in the completion or reorganization of their staffs.

### For Treatment of Burns

Visitors interested in treatment of burns with Tannic Acid in jelly or paste form should call at Booth No 67 where the Impervious Form of Cilkloid, Surgical Dressing will be exhibited as a non-adherent dressing. The Impervious Form will also be shown for non-adherent nasal packs, as well as for protective and occlusive coverings. The Perforated 'Cilkloid' will be shown as a direct dressing.

### Complete Orthoptic Equipment

The Keystone View Company will present complete orthoptic equipment in Booth 237. The exhibit will include anatomical stereographs, home and office training material, the Malingering Tests and Visual Safety Tests for highways and industries and the Ready to Read Tests for schools. New this year is the Tel-Eye-trainer with Tel-Rotor control which will be of interest to all leaders in the field of orthoptic practice.

### Inexpensive Case History Method

A system that shows at a glance the case you want how many calls you made and when the patient's history, the developments, diagnosis and treatments as well as the financial status of each case, will be shown in Booth 50 by the Medi-

### Prescription Footwear

A great variety of Walk-Over Prescription footwear will be shown by the George E. Keith Company. In the display will be samples of the firm's educational material, such as booklets on shoes, lasts, fitting and Muni Spring Arch folders on foot exercises for distribution to patients and enlarged charts for office use. These will be sent free to doctors registering in Booth 149.

### One-Writing System

At Booths 225 and 226 the McCaskey Register Company will display their One-Writing System for Physicians which includes visibility for individual active patients' records. This method protects income and provides instantly available records, professional and financial.

### Woven Names and Labels

The well known Cash Names and Labels for marking hospital linen and clothing uniforms of doctors, nurses and orderlies, will be displayed by J & J Cash, Inc. in Booth 246. Visitors will be given sample tubes of Cash's NO-50 Cement for attaching these names and labels without sewing.

### Philip Morris Cigarettes

Philip Morris & Co. Ltd. Inc. will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent are less irritating than ordinary cigarettes in which glycerine is employed. Booth 147.

### "Evenflo" Baby Nursing Unit

The Pyramid Rubber Company will again exhibit their "Evenflo" Baby Nursing Unit. With this aid there is no vacuum or back pressure to nurse against. Baby feeds in comfort and contentment. Easier for mother, too. Sanitarily protects formula and nipple between feedings. Helps to assure easy, peaceful, wholesome feeding. See demonstration in Booth 238.

### To Demonstrate Supports

Physicians and their wives will find the exhibit of Spencer Surgical and Style garments interesting. Booth 51. Nurses and representatives will demonstrate the principle of all Spencer Supports, which places weight of abdominal uplift on the pelvic girdle—not on spine, or above lumbar region. They will explain the process of individually designing each separate garment for such purposes as post-operative maternity and postpartum wear.

### Physicians Leather Goods

The Western Leather Manufacturing Company will display their entire line of physicians' leather goods in Booth 66. The exhibit will include bags, medicinal cases, vial cases and prescription pad covers. Their representative will be pleased

to discuss any personal, individual need involving leather goods of any description.

### Wright Arch Preserver Shoes

Of particular interest in the E. T. Wright & Company exhibit will be several special orthopedic lasts for men, developed and improved in collaboration with members of the profession. The special measurements and extra built-in features of support in these shoes with the authentic Wright Arch Preserver construction of their lasts supply the requirements for a of foot disorders and sub-

wide range normalities Booth 16

### OFFICE FURNITURE

#### Fine Wood Furniture

The W. D. Allison Company, manufacturers of physicians' fine wooden furniture for more than fifty years, will have on display three complete suites, as well as the popular Hynes rectal table. Visitors are urged to visit Booth 30 and see this equipment.

#### New Styles in Office Furniture

The Enochs Manufacturing Company of Indianapolis will display the latest creations in physicians' office equipment. They will have in attendance an expert on arrangement and decoration of modern medical offices. A visit to their Booth, No. 126 will prove interesting and worth while.

#### Tables for General Use

The Hamilton Manufacturing Company is to show in Booths 63 and 64 complete suites in their Moderne Nu-Classic Medical Furniture and standard Hometone Furniture. New tables will be featured which combine the examining table with a practical treatment feature. All doctors and especially all internes are cordially invited to visit this showing of modern medical furniture.

#### Feature Hydraulic Chair-Table

A hydraulic office treatment and operating chair-table, reasonably priced, will be featured by the Illinois Surgical Supply Company at Booth 75. The table may be quickly and easily adjusted to all desired positions including the true Trendelenburg. Arms are completely removable, and chair is permanently upholstered and finished in stainless porcelain and chromium. Many other items will be shown.

### PHARMACEUTICALS AND BIOLOGICALS

#### Pollen Enlarged 8 Billion Times

A most interesting feature to be seen at the Abbott Laboratories exhibit, Booths 89 and 90, is the display of enlarged pollen

granules. Each model, although 8 billion times larger than actual size, is a true reproduction of the granule as it appears under the microscope. Abbott Laboratories will also show a representative assortment of their large list of Council-accepted products. Included are Abbott's Aeridine, Metaphen, Neonol, D.R.L. Bismarsen, D.R.L. Neophrasphenamine, Abbott's Viosterol, Halyver Oil with Viosterol and others.

### Intravenous Solutions

The American Hospital Supply Corporation of Chicago and New York will exhibit Baxter's Intravenous Solutions in Vocoliters in Booth 171. Visitors are invited to call.

### Armour Exhibit

Armour and Company's exhibit will demonstrate the fact that organotherapeutic preparations unlike most other pharmaceuticals are made of highly perishable raw material which will lose its efficacy unless it is properly handled. Their booth No. 142 will depict the sources of glandular preparations, surgical ligatures, etc. in meat animals. Along with a vial of Pituitary Liquid for example will be shown the glands from which the substance is extracted. Competent men will be in attendance.

### Metrazol to Be Shown

At Booth 72 information will be available concerning possibilities of Metrazol as an antagonist to such drugs as the barbiturates, the opiates, avertin, ether and in asphyxia neonatorum. Also reports on Theocalcin in the treatment of congestive heart failure and angina pectoris and Diluclid for pain relief and cough. Other Billhuber-Knoll products to be featured are Lemigallol and Bromural.

### Ciba Specialties

Physicians are cordially invited to visit the Ciba booth No. 28 where they will find exhibits of such well known Ciba Specialties as Digifoline, Dial Nupercaine, Lipiodine and Vioform. Some interesting new uses for these products will be described by the Assistant Medical Director and representatives of the firm, who will be glad to discuss any questions.

### To Feature Cardiotonic

Urginin and Trichlorethylene will be displayed by the Calco Chemical Company in Booth 184, also the cardiotonic Urginin representing the combined water-insoluble quill glycosides (Scillonin A and Scillonin B) in approximately equal proportions and trichlorethylene-Calco in 1 cc frangible mesh covered ampules, for relief in facial neuralgias.

### Dubin Aminophyllin

In Booth 61 duly demonstrations of the easy solubility of Dubin Aminophyllin will be given by its originator. The drug is useful as a coronary vasodilator, myocardial stimulant and diuretic. Literature and samples will be available.

### Dependable Digitalis Preparation

Visitors are invited to call at Booths 227 and 228 where they will find exhibited products of Davies Rose & Co. Ltd. One outstanding production of this firm's laboratory to be shown is Pil Digitalis (Davies Rose). The physiological dependability of these pills has won for them widespread recognition.

### Improved Tablet Making

The Drug Products Co. Inc. (Booth 200) will demonstrate the advantages of their Pulvoids by reduction to powder under thumb pressure. They will show how the rapid disintegration results in prompt assimilation of medicaments.

### Recently Developed Uses of Lipiodol

Physicians who visit Booth 169, of E. Fougere & Co. will be offered an excellent opportunity to discuss the recently developed uses both diagnostic and therapeutic in which Lipiodol Lafay has been employed. Digitaline Nativelle will also be displayed. Information will be available concerning the research recently completed surrounding this stable Glucoside of Digitalis purpurea.

### Subcutaneous Liver Extract

Their Subcutaneous Liver Extract is to be featured by Chappel Laboratories in Booth 39. This preparation lends itself readily to office and hospital routine where a trained assistant can administer it with ease and safety. The product has been reported in current medical literature. Reprints and complimentary supplies will be available to physicians.

### Sodium Bicarbonate U S P

Church & Dwight Co. Inc. who for 90 years have concentrated on producing pure sodium bicarbonate will exhibit in Booth 137. Here they will show those dependable old products that have stood the acid test of time since 1846—Arm & Hammer and Cow Brand Bicarbonate of Soda.

### Intravenous Products

The Cutter Laboratories in Booth 46 will exhibit their Council Accepted prepared and ready to use Dextrose and other solutions in Salfitask containers. Demonstrations will be held to show the proper technique for putting these flasks in operation and to demonstrate the ease and simplicity of their use to the physician. A complete line of Council Accepted Cutter biological products will also be included.

### "Medicines of Rare Quality"

A call at the Hoffmann-LaRoche Booth No. 151 may very well be an essential part of every visitor's itinerary. Anticipating unprecedented interest in their display this year, Roche assures that there will be in attendance the usual adequate staff of

representatives of the Medical, Scientific and Research Divisions to permit of uninterrupted personal discussion of 'Roche' 'Medicines of Rare Quality'.

### To Demonstrate Filtrair Method

The newer methods of administration of parenteral solutions will be featured by Hospital Liquids Inc. in Booth 103. Interesting demonstrations of the Filtrair method will be on display and an attractive booklet on parenteral administration reviewing all the literature to date will be available to physicians. Competent representatives will be in attendance, and they will be glad to discuss the many problems of parenteral therapy.

### All About Mercurochrome

Hynson Westcott & Dunning Inc. in Booths 94 and 95 will have an interesting display featuring Mercurochrome in its respective dosage forms including Mercurochrome Surgical Solution for prooperative skin disinfection. In addition numerous scientific diagnostic appliances and apparatus will be exhibited. Literature and samples will be available to doctors who are not already familiar with products exhibited or who wish a trial supply.

### Ampoule Preparations

Their Council Accepted Ampoule preparations particularly their ampoules of Dextrose (d. Glucose) 50%, Sodium Cacodylate and Calcium Chloride will be exhibited by Lakeside Laboratories, Inc. in Booth 1. Members of the research staff will be present to demonstrate the chemical, bacteriological and physiological methods used to insure the purity, sterility and safety.

### New Scarlet Fever Antitoxin

Lederle Laboratories will feature one of their new series of Globulin Modified Antitoxins, a 6000 therapeutic dose of Scarlet Fever Streptococcus Antitoxin contained in a vial of 3 1/2 cc—together with their latest contribution to Liver Therapy—the 1 cc Concentrated Solution Liver Extract Parenteral which contains active substance obtained from 100 grams of Liver (Booths 59 & 60). Staff representatives will be in attendance to answer technical questions.

### Convention Package to Be Mailed

Visitors are cordially invited to call at the booth of the Malthie Chemical Company No. 104. Questions will be answered fully about Calcereose, the original brand of calcium cresotite U S P. The firm will be glad to send a splendid convention package to all those who leave their name and address.

### Treatment of Syphilis

Reprint of a scientific report 'Standard Treatment Procedure in Early Syphilis,' will be available at the Merck Exhibit. A schedule of treatment based on the use of arsphenamine or neosalvarsan as the foundation of the recommended treatment will be given. Also Cebione (cevitamic acid Merck) pure crystalline vitamin C, will be shown in Booths 31 and 32.

### Cod Liver Oil Research

The Malthie Company will demonstrate in Booth 12, the various steps involved in the manufacture of Maltine with Cod Liver Oil and will show evidence that the vitamin A value of cod liver oil is enhanced two fold when administered as Maltine with Cod Liver Oil. Charts and illuminated photographs will show results of recent laboratory research on this subject.

### Biological Products

The National Drug Company will exhibit a complete line of antitoxins, curative serums, antigens and vaccines and will demonstrate the various steps used in the refinement and concentration of Antitoxins. They will demonstrate the Sabouraud method for determining the type of pneumococcus in pneumonia patients and the agglutination testing of Typhoid Vaccine. Particular attention will be directed to Hys Fever and Poison by Antigens. Booth 26.

### Puritan Maid Products

The Puritan Compressed Gas Corporation, pioneer medical gas manufacturers will exhibit in Booth 172. The firm manufactures the Puritan Maid brand of Nitrous Oxide, Ethylene Oxide, Carbon Dioxide and Carbon Dioxide-Oxygen Mixtures and are also distributors of leading makes of oxygen tents, nasal catheter outfits and anesthetic apparatus.

### Famous Painting to Be Shown

Owing to many requests from members of the medical profession, Petrolagar Laboratories Inc. will again exhibit the life like sculptural reproduction of the Doctor after the famous painting by Sir Luke Fildes, R.A. All physicians attending the meeting are cordially invited to view this renowned three dimensional work of art by Paulding and Ingels in the room provided for it. An unusually attractive pharmaceutical exhibit designed especially for the 1936 meeting will also be shown. Booths 8, 247, 248 and adjoining room.

### Many Squibb Products Shown

Whether their interest is in endocrinology, metabolic disorders, anesthesia, genito-urinary infections, allergy, nutrition or immunology, physicians attending the convention will find much of interest in the various Squibb Products useful in these various fields. A unique opportunity is afforded physicians to examine and discuss many of the recent research contributions which lend promise of marked clinical usefulness. Competent representatives will be in attendance at all times to answer inquiries. Booths 122, 123, 124 and 125.

### All About Insulin Therapy

Insulin therapy and the newer developments in the production of this important therapeutic agent will be one of the features of the exhibit of Frederick Stearns & Company, Booth 152. Another interesting new product which will be demonstrated at this exhibit will be Neo-Synephrin Hydrochloride, a vaso constrictor for the relief

**THE KANSAS CITY SESSION**

---

In this issue of THE JOURNAL appears the usual advance information relative to the annual session of the American Medical Association, which is held this year in Kansas City, May 11-15. The physicians of the Kansas City area have for some years established an enviable reputation for efficiency in the management of medical sessions and for hospitality toward the stranger within their gates. The prospects for the Kansas City session indicate that this reputation will be enhanced and multiplied manifold by the results of the first session of the American Medical Association to be held in Kansas City. Public officials, the hospitals, the medical profession and the community generally are all contributing their utmost to insure the complete success of this occasion. The professions of both Kansas and Missouri are enthusiastically interested. A local committee on arrangements has been developed so completely that members of the local profession are intimately associated with every one of the activities of the convention week.

Last week the reports of the officers and trustees of the Association were made available in THE JOURNAL. A special feature was the publication in boldface type of summaries to each of the sections of the reports. These were planned so that physicians generally might be aware of the numerous problems in the field of legislation, social welfare, economics and medical science which form the concern of the official bodies of the Association. No doubt many of these problems will receive special consideration by the House of Delegates at the Kansas City session.

Attention is called to the opening general meeting, at which there will be not only the addresses of the officers of the Association but also announcements by the governors of Missouri and Kansas and by representatives of local medical organizations. The general clinical meetings, which have in the past few years attracted thousands of physicians, include on this occasion two notable representatives from abroad—Lord Horder and Afranio do Amaral—and clinicians chosen

to give authoritative reviews in medical progress in many fields of current interest. The section programs include other distinguished visitors from foreign countries.

The list of entertainments indicates the greatest number of alumni and fraternity dinners and luncheons officially scheduled for any annual session. Moreover, the entertainment committee has scheduled golf tournaments and skeet and trap shooting tournaments on an ample scale.

The programs of the scientific sessions which are here included and the detailed announcements of the Scientific Exhibit speak for themselves. Especially interesting, however, are the symposiums scheduled in the sections and the special exhibits on traffic accidents, fractures, diabetes and other special topics, developed under the control of the exhibit committee of the Association.

The arrangements for women include not only special sessions of women's medical organizations but also an extensive program for the Woman's Auxiliary.

The new auditorium which Kansas City has built for the holding of conventions is closely adjacent to the excellent hotels and provides under one roof accommodations for practically all the activities of the session. The pictures of the auditorium that accompany the special article are but a slight indication of its beauty, its comfort, and the other modern qualities which it provides. Kansas City is the key city of the Southwest. The session will therefore attract many physicians who are not regularly attendant on annual sessions of the Association held in the East, in the North or in the Far West. The climate of Kansas City in May is salubrious. Physicians who have made regular attendance on the annual sessions of the American Medical Association a duty and a high point in their medical lives have come to realize the great significance of these sessions in individual medical advancement.

---

**RESEARCH ON THE GONOCOCCUS AND  
GONOCOCCIC INFECTIONS**

The report of a special committee appointed to investigate the present status of research on the gonococcus and gonococcic infections has been recently released.<sup>1</sup> The two years of study from 1933 to 1935 were aimed at (1) ascertaining the amount, quality and trend of investigation on the gonococcus and the diseases it causes, (2) analyzing and correlating information derived from publications and interviews in order to evaluate accomplishments and to discover promising lines of research, and (3) assisting in laying a basis for the solicitation of financial support commensurate with the biologic, medical, social and economic importance of the subject. Some indication at least of the present

---

<sup>1</sup> Thomas, Ruth B. and Bayne Jones, Stanhope. Report of the Committee for Survey of Research on the Gonococcus and Gonococcal Infection. *Am J Syphonor & Ven Dis* (suppl) 20:9 (Jan) 1936.

state of knowledge concerning the gonococcus and gonococcic infections and of the problems that are engaging the attention of investigators in laboratories, clinics and private practice has been made. As part of its work a list of the persons in the United States who have been studying the gonococcus during the last few years has been recorded. This list is not yet complete and has therefore not been reproduced with the report. The individual names in the list number 180. Not all are doing fundamental or important work on the gonococcus and gonococcic infections, but a number of the studies have resulted in definite gains in knowledge. No estimate of the amount of money now being expended on these investigations could be attempted. The evidence, however, was that, with few exceptions, the available money is scattered in relatively ineffective small sums. There are few if any large appropriations of funds for the support of research on the gonococcus.

A review of the literature indicates that much confusion of thought on many phases of the problem still exists in spite of every effort to achieve lucidity and coherence. Much of the literature expresses results or conclusions founded on work that is poorly controlled. In this respect according to the report, the clinical studies rank on the whole below those carried out in the laboratory. Even though the available factors are more susceptible to control in laboratory studies than in those made on man, there is no apparent reason why the same quality of intelligence cannot be applied to the two fields. The writers of the report evidently felt that this is only exceptionally the case. They also concluded that, while the number of papers on this subject is voluminous, many of them are superfluous and merely serve to confuse the more important issues. Negative or inconclusive results are not so likely to be published as those which are considered positive, hence many workers who evaluate their results by exacting standards tend to publish their reports less frequently than those with a less well developed critical sense.

Some studies, especially those relating to methods of therapy, are financed by commercial establishments that may have an interest in the product on trial. Under these circumstances, completely objective evaluation of the results is unusually difficult.

Unsolved problems worthy of investigation exist in almost every section of the field. Two fundamental problems the solution of which would appear to lead to the greatest progress are (1) further clarification of the biochemical nature of the gonococcus and the products of its metabolism and (2) the production in animals of gonococcic infections similar to those found in human beings. These two fundamental problems have subdivisions each of which could well serve for the concentrated study of large groups. The answer to the first problem might enable a better understanding of the mechanism of the production and the chemical nature of toxins. It might also provide a rational

method of preparation of vaccines and antigens as well as the possible development of therapeutic methods not yet perceived. The second question is if anything more important in that it would allow certain features of the infection to be more clearly understood. Among the more important of these are the limits of the incubation period, the variations of virulence of different strains, the mechanism of invasion, the mechanism of pathogenicity, the variations of individual resistance, the factors of immunity, and the accurate evaluation of therapeutic and prophylactic measures.

Periodic reviews of the status of a problem or a group of problems helps to avoid a vast amount of unnecessary repetitions or uncritical work. All those interested in any of the research problems connected with the gonococcus should carefully familiarize themselves with this report.

#### POTENCY OF ANTIANEMIC PREPARATIONS

The establishing of comparative potency of preparations of liver and stomach used in the treatment of pernicious anemia is difficult. Recently, after extensive consideration, the Council on Pharmacy and Chemistry<sup>1</sup> developed standards that will permit direct comparison of the antianemic potency of such products, these standards are based on the reticulocyte production resulting from daily administration of the extract under test to patients in exacerbation. Because of the difficulty in applying these clinical tests, insufficient time has thus far elapsed to establish the potency of all the antianemic products in New and Nonofficial Remedies, it is expected that this will be accomplished in the near future.

The amount of liver employed in manufacturing a given amount of extract is of little importance compared to the potency per given weight or volume of the final extract. However, until the Council established its new standards the only method available to indicate potency was to state the amount of liver from which the product was derived, this, of course, led to wide divergence in many cases between the assumed and the actual antianemic effectiveness. This was particularly the case with products made by new methods (for instance, autolysis) which were claimed to enhance the potency. Contrary to such claims, products made by autolysis were found by Castle and Strauss<sup>2</sup> to be less active than the amount of liver from which they were derived. This led to controversy over the value of autolyzed liver preparations in the treatment of pernicious anemia.

Elsewhere in this issue is an article by Klumpp<sup>3</sup> reporting results that confirm the essential observations

1 Standardization and Labeling of Liver and Stomach Preparations for Use in the Treatment of Pernicious Anemia. Report of the Council on Pharmacy and Chemistry. J. A. M. A. 105:1269 (Oct. 19) 1935.

2 Castle W. B. and Strauss M. B. Effect of Autolysis on Potency of Liver in Treatment of Pernicious Anemia. J. A. M. A. 104:798 (March 9) 1935.

3 Klumpp T. G. The Treatment of Pernicious Anemia with Autolyzed Liver Concentrate. This issue p. 1245.

of Castle and Strauss and indicate the amounts of the autolyzed product necessary to initiate remission and to maintain a normal erythrocyte level in pernicious anemia. Klumpp concludes from his studies that an amount of the autolyzed preparation derived from a given amount of liver is more potent than the amount of liver extract made in the usual manner (without autolysis) derived from the same amount of liver. The evidence for this claim does not appear to be conclusive. Even granting the validity of Klumpp's conclusion, this does not mean that gram for gram of the final preparation the autolyzed preparation is more potent than the ordinary extract. The contrary is the case, as the process of making the autolyzed product is such that the material obtained from a given amount of liver weighs more than three times as much as the extract. The foregoing illustrates the confusion that is possible in estimating comparative antianemic potencies and emphasizes the necessity for standards such as the Council on Pharmacy and Chemistry has devised.

The activity of a given amount of the final product is the important consideration in the therapeutic use of an antianemic preparation, the amount of raw material used in its manufacture is a secondary consideration which concerns chiefly the efficiency of the process employed and thus in some cases the cost of the final material.

#### VITAMIN C AND CHLOROPHYLL

Several years ago it was pointed out<sup>1</sup> that there is in general a parallelism between the distribution of vitamin C and that of chlorophyll and perhaps other plant pigments. The green portions of plants were especially excellent sources of cevitamic (ascorbic) acid. Recently<sup>2</sup> a further study of this relationship has been made. Guinea-pigs fed a basal scurvy-producing ration were given as a supplement either the green leaves, the colorless leaves or the roots of certain plants, including carrot, turnip, endive, lettuce, onion and beet. The effect of the various supplements on the body weight, the appearance of hemorrhages at the joints, loosening of teeth, hemoglobin and erythrocyte content of the blood, and the cevitamic acid content of certain organs at necropsy was determined. In addition, the cevitamic acid content of the supplements was determined chemically by titration with 2,6-dichlorophenol-indophenol. In every instance the vitamin C content of the chlorophyll-containing portion of the plant exceeded by as much as ten times that of the colorless portions or the roots. The biologic responses likewise agreed with these results. Animals receiving the chlorophyll-containing portions of the plants remained normal, whereas those fed the same amounts of the nonchloro-

phyll containing portions or roots developed typical symptoms of scurvy. There was a progressive decline of body weight, development of hemorrhages at the joints, loosening of the teeth and a marked lowering of the hemoglobin content and number of erythrocytes in the blood. Analyses of the vitamin C content of the tissues of the animals at necropsy yielded confirmatory information. The organs particularly the suprarenals, of the guinea-pigs fed the nonpigmented plant supplement showed a distinctly lower cevitamic acid content than did those of the animals receiving the chlorophyll-containing supplement.

#### THE NORMAL RANGE OF THE LEUKOCYTE COUNT

The variation in the peripheral blood leukocyte count has been widely recognized, especially since the study of Sabin and her collaborators<sup>1</sup>. That classic study, however, was published in 1925, and much of its force has been dissipated in the intervening time. The principal conclusions reached were that there is a characteristic rhythm of the total white blood cells with an interval of approximately an hour's duration, the total number of the cells varies in the proportion of 1 to 2, it is increased in the afternoon, regardless of whether or not food has been taken, and the entire increase is the result of an increase in the number of the neutrophilic leukocytes. Those conclusions were based on a study of six apparently normal individuals at frequent intervals over a considerable period. The necessity of renewing and extending this work is evidenced by the recent report of Juster<sup>2</sup>. In beginning an investigation of chronic rheumatic heart disease he found it necessary to redetermine the range of the leukocyte count in normal subjects under standard conditions. His group consisted of eleven persons between the ages of 17 and 50. Seven females and four males were studied for a period of from eleven to ninety-eight weeks. The observations were made weekly between 10:30 a. m. and noon. Unusual physical exertion was avoided, and there was no exposure of the hands to extreme heat or cold prior to the drawing of blood. The variations of the leukocyte count when charted as a curve were strikingly similar in nine of the eleven patients. The two others were so different that they were considered abnormal in spite of the fact that there was no physical basis to account for the abnormality. These individuals were, however, in a more emotional state than the others. Of the nine patients retained as normal, all the counts were below 11,000 in the upper limit and all, with one exception, above 4,000 in the lower limit. For practical purposes, therefore, the normal range of the leukocyte count is between 4,000 and 9,000, a ratio of 1 to 2 and similar to that found by Sabin and others. The curves did not show any individual pattern but appeared to fall within two groups. The first group included seven patients, and the second group of two patients did not have as wide

a range of variation as those in the first group. Sex, season and age within the limits of the group studied appeared to have no influence on the leukocyte count. The variations illustrated by this study offer nothing new or surprising, but they serve to confirm and emphasize the facts of variation previously known.

What is the Social Objective of the Young Physician

DR. NATHAN B. VAN ETTEN, New York. This article appeared in full in *THE JOURNAL*, March 7, page 772.

### Some Observations on the Social Background of Medical Practice in Great Britain

RICHARD E. SCAMMON, PH.D., Minneapolis. The information presented here is based on the experience of a number of years, of which a part of each has been spent in Britain in an attempt to study the laws governing English practice. I view the English scene through American eyes, but it should be remembered that while many years' association with physicians has led me to take a sympathetic interest in their problems, I am a layman.

The various forms of medical practice existing side by side, recognized and unrecognized in Britain may be listed as follows:

1 The Highlands and the Isles service is limited to the Scottish Highlands and to the string of islands along the northwest coast. It is a purely social service. It appears to be excellently administered and attracts a high type of medical graduate. These fine and sturdy people, even with the rigid practice of Scots' thrift, do not find it easy to exist. The conditions in this area strike me as resembling those in certain parts of Alaska which I have visited where any government agency dealing with medical care came to the aid of the more or less marooned population in case of an emergency.

2 The second form of free medical service is that offered by the Poor Law Medical Staff of recognized paupers. These Poor Law medical officers are estimated to have the care of something like 300,000 sick persons.

3 There still remains in some of the remote valleys of Wales a small amount of private contract form of practice, which has grown up in the isolated mining communities, quite independent of regular medical practice.

4 Insurance or panel medicine requires the full time of the practitioner. This form I judge is relatively limited and is found mainly in the "distressed areas" and the more poverty stricken portions of the great cities.

5 Panel practice employs a part of the time of the practitioner who also conducts a private practice. It is exceedingly hard to differentiate between these last two groups. In fact, physicians seem to change from one to the other under the influence of a variety of circumstances. It is generally estimated that about two fifths of the registered physicians are engaged to some extent in panel practice. Panel practice is limited to employed persons engaged in manual labor or receiving incomes of less than £250 annually. In all perhaps two fifths of the British population are entitled to insurance through the panel system although, as will be pointed out later, I think a considerably smaller proportion make use of it. Any physician who is on the rolls of the General Medical Council may apply for a panel. He is limited under ordinary circumstances to a maximal number of 2,500 insured patients and generally

has less than a thousand. A panel physician is not required to perform all types of medical service. There is a small list of relatively minor surgical procedures which fall within his duties. But beyond this he may charge his panel patient for special services. In addition to other duties, the practitioner holding a panel is required to order medical appliances, drugs and the like, and the value and extent of these orders are adjudicated by the Panel Committee, which is made up of physicians. The panel physician must also undertake the task of certifying for sickness and disability benefits of patients under his care. The makeup of the several administrative boards under which he must work is extremely complex, including regional medical officers under the employ of the Ministry of Public Health, an advisory body which is medical in its personnel, and the approved society to which the patient must belong. The cost of the service is split about two fifths to the patient, two fifths to the employer and one fifth to the government. It is also somewhat difficult to estimate the income that the physician receives from his panel work. He is allowed 9 shillings or between \$2.25 and \$2.50, a year per person on his panel. This would work out in the case of the average physicians who engages in panel practice to about \$2,200 (without attempting to equate this sum into American purchasing power). It is the opinion of a number of persons, however, that the median earnings are considerably higher.

6 The sixth type of medical practice is one exactly the same as our own, in which the physician carries out the functions of his profession in the usual manner, taking private patients. Data collected by the National Health Insurance Commission over a decade ago indicates that the average income of a fairly successful practitioner, not a specialist, varied from about £1,200 to £1,400 and that his net income was perhaps in the neighborhood of £800.

7 The seventh form of medical care is that furnished by the great privately endowed hospitals, as distinct from those provided for the pauper sick. Most of the service here is purely charity work, given by men either engaged in purely private practice or in part panel and part private work. The great private hospitals of Britain seem to be encountering many difficulties in their fiscal operation. All sorts of devices have been used to augment this income.

8 The eighth and final form of recognized medical care is concerned primarily with public health and is carried out through the agency of medical officers of public health. The necessity of an adequate sanitary service is obvious.

These categories represent some of the legitimate forms of medical care. One may also list those that fall without the pale of accepted practice.

1 Irregular practitioners seem to be rather scarce in Great Britain. While a few osteopaths, chiropractors and unregistered physicians may carry out their activities, they are not obvious.

2 Druggists are said to prescribe and diagnose over the counter.

3 The sale of "patent" or proprietary medicines seems to me to be relatively small.

4 On the other hand the wide exploitation and advertisement of so-called health or tonic foods indicates a large consumption of this pseudomedical commodity.

5 There is another form of practice almost unknown to us at the present time but, I think, very prevalent in Britain. This is folk medicine. Medical traditions and remedies, generally worthless, but handed down from generation to generation, seem in very common use among a large mass of people. Practically every cook book includes a host of so-called remedies, often for maladies that we would think required the expert physician's care.

One gains the impression that the personnel of the service for public health in Great Britain is excellent. In fact, this service which has been built up over many years, has proved itself so efficient that public opinion is behind it and dismissals which in theory could be made at any time occur only in cases of gross inefficiency or misconduct. Since both the central government and the minor administrative units have built up a modest but sufficient annuity system, the service attracts and holds able men.

The rulings of the General Medical Council may be regarded as the basic code of the practice of medicine in the United Kingdom. Added to this are the regulations of the British

Medical Association, which is a limited liability company not organized for profit and which lays down a still stricter code. There is a third and even stricter code maintained by the Royal College of Physicians. While a licentiate may apparently own an interest in a private hospital, this seems forbidden to members and to fellows. Likewise fellows may not enter into partnerships, may not sue for fees, may not attempt to sell their practices, and are forbidden to engage in trade.

Naturally this complex situation did not arise without a long and complicated history. Although it may seem after the passage of 400 years that the transition from the medieval to the modern system was abrupt and dramatic, the records hardly bear out this concept. A century ago the medical situation in Great Britain had become so antiquated and complicated that change seemed imperative. Health, it appears, had much improved, as had the quality of medical practice, but the conditions governing the health professions were chaotic. There were some eighteen licensing bodies with variable powers and areas of authority, some of them overlapping. The laws governing medical practice represented an accretion of some two centuries and were often in conflict. Medical teaching was at a low ebb at the great traditional universities. There were at least three classes and a number of subclasses of medical men. It is not surprising that a determined effort was made to clear this situation. The reform did not start with the universities or the older corporations of physicians or surgeons. It began primarily with the surgeon-apothecaries or general practitioners of the country, who associated themselves in various groups such as the National Association of General Practitioners and the Provincial Medical and Surgical Association, which was formed at Winchester in 1832 and which more than twenty years later became the British Medical Association. The leaders of this movement, like most persons desiring improvement in conditions, wanted a root-and-branch action sweeping away all older and traditional forms and the constitution of a quite remodeled scheme of medical education, licensure and code of practice. But this is not the British way. Select committee after select committee of parliament was appointed to inquire into the problem, bill after bill was introduced, and finally in 1858 a full quarter century after the movement had become active, the medical bill was passed. The medical act of 1858 was frankly a compromise and more than a generation passed before it became generally acceptable. It established the General Medical Council. In the meantime the Poor Laws had been reconstructed again and again. After a few years struggle with contract practice, this form was given up in favor of an organized medical service of properly qualified men to treat the pauper sick. There had also arisen a system of voluntary medical insurance in the so-called Friendly Societies, which operated on the contract basis, under boards of lay persons, hired physicians as cheaply as possible, and did not hesitate to advertise and canvass to increase their membership. The British Medical Association contested this practice and in 1894 secured an inquiry which resulted in a declaration that it was unprofessional for a registered physician to be associated with a canvassing institution. Still these organizations continued to operate until the passage of the Medical Insurance Act of 1911.

It is difficult to give an accurate account of the establishment of the National Insurance Act, or the panel system. It occurred in that peculiar phase of English history stretching from 1908 to 1914, which George Dangerfield has just described in his book "The Strange Death of Liberal England." All sorts of changes, social, political and economic were in the air. The plan was proposed by the chancellor of the exchequer, who after a two months study of the German insurance system—in an interval when, according to his own statements, he was harassed with the possibility of war—outlined the National Insurance Act which was soon coupled with the Unemployment Insurance Act sponsored by Mr. Winston Churchill. The original form was close to the German one but a determined resistance by the medical profession led by the British Medical Association resulted in profound modifications. The Health Insurance Act became law in 1911 but more than twenty amendments of it have been passed in the quarter century of its existence.

The British Medical Association has played an important part in all health matters in Britain. Most of the numerous modi-

fications of the insurance act that have protected and improved the lot of the physician in panel practice are the outcome of its activities. The association has insisted on a high professional code among its members and it seems to have been extremely successful in maintaining this code. Finally, the association has succeeded, in an effort extending through generations, in raising the social status of the medical practitioner to an entirely new level. In military life it has made the physician an officer and a gentleman and in civil life a gentleman and a person of respect.

#### DISCUSSION

DR. WILBURT C. DAVISON, Durham, N. C. There are two reasons for the difference in the situation in England and the situation here, first, the size of the country. After all, England is only as big as North Carolina, and the population is much more uniform. I think it was said by General Cumming at one time, when some of the British were criticizing some of the health conditions in this country, that if we had a country as small as Great Britain we would take it out and whitewash it every morning. Second, the difference in the character of the people. Not only do they differ from our people in being much more uniform, but through the last eighty years there has been a tremendous effort on the part of the General Medical Council to bring out an appreciation of the differences in medical practitioners. There are about five different degrees in England. There is the L.S.A., Licentiate of the Society of Apothecaries, the lowest medical degree, and the British recognize that if they have a sore throat they may call in a Licentiate of the Society of Apothecaries but, on the other hand, if they have a dangerous illness they realize that they must call in a practitioner with a higher degree. Then there is L.R.C.P. and L.R.C.S., then the Bachelor of Medicine of London or Oxford or Cambridge, the M.D., a degree granted some years later, and then the Fellowship in the Royal College of Physicians and Royal College of Surgeons, and the people recognize the difference in those different groups. Also, they realize that a man's hospital affiliations give some index of his ability. That is, if a man in London is on the consulting staff of St. Bartholemew's Hospital or St. Thomas's Hospital he commands respect much more than a man who has no hospital affiliation. A third factor is the fact that the medical profession in England comes almost entirely from the upper middle class. In this country any one can study medicine provided he can borrow or work his way through medical school. In England that is not possible except in extreme instances. In this country we have a larger number of better physicians because we are drawing from a much wider group of society. On the other hand it probably means that we have a fair number of worse physicians, whereas the English average is much more uniform. The two types of medical practice that have been talked about a good deal as being applicable in this country are the panel system and the system of contributory hospital schemes or hospital insurance. I was a medical student in England three years and was there at the time the panel system started. It was unsuccessful the first two years, but at present most of the physicians I know operating under the panel system are satisfied with it. They have eradicated many of the difficulties and made many improvements, and I think it is certainly to the advantage of the public and to the medical profession to have this panel system but whether that would work in this country is an entirely different problem. I doubt that it would. One of the reasons for the success of the panel system, in addition to the uniformity of the profession and the authority of the General Medical Council to iron out difficulties is the fact that the people themselves started the panel system through the friendly societies. They got together and contributed a certain amount a week to get medical care they were unable to purchase otherwise. The same thing is true of the voluntary hospital insurance plan. The people themselves, through their parishes or through their employees organized and contributed voluntarily to get hospital care. In this country I doubt very much whether such a voluntary movement would be possible. One interesting situation is the thing going on in the bigger cities. The contributory schemes are helping such hospitals as St. Bartholemew's and St. Thomas's but are not completely covering the situation so it has been necessary for the London County Council to establish charity hospitals or county hospitals similar

to Cook County Hospital here or Bellevue in New York, and many of the patients not able to finance themselves through contributors' schemes are going to the county hospitals. They are presenting great difficulties to the British medical schools. The schools there haven't shown the same disposition to affiliate with the charity hospitals as the schools in America have.

### Instruction of Students and Interns in the Legal, Social and Economic Influences Affecting Medical Practice

DR STANHOPE BAYNE-JONES, New Haven, Conn. This article will be published in full in the *American Medical Association Bulletin*.

### The Present Curriculum and the Aims of Medical Education Are They Compatible?

DR LANGLEY PORTER, San Francisco. Too little acquaintance with living forces that are changing the social order before our eyes and too great devotion to sifting out the few grains of worth from the chaff of dead bibliographies are but two among many handicaps that are loaded on the student.

Can the curriculum be purged of the rests and residues and be recast so that it will equip men to meet the medical service needs of the modern community? Can the course in medicine be improved so that the student is trained to understand all things needed to protect health and to prevent disease in individuals and communities? If such aims are to be accomplished, the medical schools must be prepared to train four types of graduates. The first group consists of men whose temperaments and aptitudes fit them to replace the vanishing general practitioner, men able to administer all available medical services to individuals and to families. Second every medical school should be prepared to train a part of its student body to engage in public health activities. A third obligation that rests on the medical school concerns its duty to provide a limited number of well trained specialists and to revise present conceptions about what constitute proper and legitimate fields for specialization. Today by far too large a proportion of medical men are specializing in very narrow fields. Finally, it is of the utmost importance that the need for highly trained investigators and teachers be remembered. Whether the students are to be practitioners, health officers, specialists or investigators, their student life should be passed in close companionship and they should be guided by the hope to achieve a pattern expressed in a schedule of studies that emphasizes principles rather than details that points out opportunities and awakens interest and enthusiasm, that illuminates the unities of medicine and minimizes the values of factual knowledge if unrelated to great integrating principles.

To carry out its proper functions, the medical school must be prepared to produce in proper proportions, recruits for each of these proposed groups and the schedule of studies in the curriculum must reflect the philosophy behind the plan and the ability to carry it out. Certainly a curriculum representing a mosaic of independent specialist courses does not, nor can it, reflect such a philosophy nor is it likely to guide students to the opportunities that can best be used to form the background essential to the creation of great medical practitioners.

Among the residues that hamper improvement in medical training hardly any is more deplorable than the semester system. This holdover from the organization of grammar school teaching may be popular with instructors who like to reserve one semester entirely for their own research work, but in practice the result too often is that the student's time is wasted and the man who desires to repeat certain work is dissuaded from doing so because of the long wait imposed on him. Often the resulting lack of preparation handicaps him so that later he abandons medicine or, managing to get by, he remains mediocre. Another unfortunate residue, less common than formerly, is the idea that one department in the medical school can carry on its work without relation to the teaching of another.

Of what value are the misnamed "preclinical" sciences to medicine unless the physician can bring them to the clinic to the bedside? How is the student to be taught that the unfortunate distinction formerly made between laboratory studies and physical examinations is heretical—that it is another "residue" left over from the days when the so-called preclinical

man and the ward-walking physician misapprehended and disliked each other? How can the student be made to see that laboratory examinations alone are no more scientific, no more revealing, than the facts to be gathered from sight, sound, touch and smell? The neophyte arrives at the idea slowly. Often he does not get it at all, and so he comes to estimate laboratory observations as a sort of magic, infallible and contradictory of all other observations, even of common sense, or else to regard them as a useless burden to be avoided even, if need be, by dishonest expedients.

The primary error behind this weakness was laid long ago when increasing factual detail made it expedient that the old Chair, then known as the "Institutes of Medicine," be divided into anatomy, physiology and biochemistry, and it was exaggerated when ever increasing new facts brought new subjects that it was felt had to be included in the curriculum, until today every student is taught by a score of specialists, each armed with his own textbook and journal, and each, when examination time comes, demanding that the student prove himself almost as much a master in his special field as is the master himself.

It may be that what is needed is a plan for medical education in which the total hours available are treated as a single course, a course in medicine which attempts to integrate all the sciences and arts utilizable in practice and which aims to produce a total based on a pattern of guiding motifs which will appear in the very beginning of premedical education and be carried through until the completion of the student intern year. The major guiding motifs would naturally be physiology and pathology. Psychology, economics and sociology would be essential.

Through the clinicopathologic conference, a most important link between the fundamental and the medical sciences has been maintained, to the enrichment of the art of medicine. In some schools this has been followed by elevating clinical anatomy above its former didactic position and advancing it to a point at which the anatomist makes ward rounds with the surgeon. He is ready to consult with him on problems involving anatomic knowledge, and his laboratory is available to provide dissection material. He is ready to confer with and advise such of the students and staff as need exercise in anatomy. In some schools the same sort of arrangement is being opened to biochemists, physiologists and bacteriologists, that they may cooperate with medical, pediatric and obstetric teachers and clinicians in ways that are stimulating and fruitful. The same sort of integration is being applied to the study of special or complicated subjects. Men from all departments interested, who can bring special knowledge to bear in the intricate problems concerned, are constituted into committees which confer and discuss the important implications in open sessions. Such developments are bound to reflect themselves in curricular changes. May it not be that the time has come to go over the top, to follow more dynamic plans of campaign strategy?

### DISCUSSION

DR JOHN WICKOFF, New York. Dr Porter has asked a question, and I wonder whether the question can be answered. Surely there is no such thing as a single curriculum. I wonder if there should be such a thing as a single curriculum. Must not curriculums always be individual things? The discussion this morning has pointed out that the scope of medical education has enlarged. After all doesn't a curriculum depend on three sets of bearings? First there is the student's preparation before he comes to medical school, second, the changes which we have been discussing today, the changes in medicine, and third the changes in his education after he leaves medical school. Consequently, in order to meet these variables, a curriculum must be constantly changing. In each school a curriculum must modify itself continuously depending on changes in its physical facilities and changes in its personnel, and unless a school is constantly conscious of the fact that these facilities are changing, that certain members of the faculty are growing older, that there are certain changes being made in the faculty, that the curriculum cannot be the best curriculum there may be in that particular institution. The greatest fault in the making of a medical school curriculum is the tendency of one institution to copy the curriculum of another institution, because of the fact that our institutions are in different places, that we have different relationships. Dr Porter spoke of the semester system

Of course, the putting of subjects into compartments is the thing which all of us have to fight. However, it seems to me there is not much more difficulty when a block system is used than when a course may extend over two and one-half years.

There is a point that I should like to stress. It seems to me that in every curriculum there should be an effort to put increased responsibility progressively on the students of medicine. I can think of no profession that has to carry the responsibility that the physician has to carry. The intern on the day he enters the hospital, has to take over a load of responsibility, and unless we take a good deal of care I think our curriculums are apt to be so arranged that our student is not given such responsibility, and certainly he cannot learn responsibility by precept, he must learn it from practice. Of course if a curriculum is going to be a changing thing there must be some type of an organization as Dr. Porter has said, to supervise it. Here I believe there should not be one single guide. I think that depends on the institution. In some institutions it may be a benevolent despot. In other institutions it may be a wideawake committee. There is one thing it should not be, and that is a committee which is simply made up of certain officers in the institution that is it should not be a committee which is simply made up of department heads, because when a curriculum committee is made up that way there is danger of its becoming frozen and the curriculum is not a living thing as we would like to have it.

DR S P LUCIA, San Francisco. Just a remark in relation to Dean Wyckoff's remarks. We do not wish that a curriculum will be fixed, that it might be used in other medical schools. The principles under which a good curriculum is operating or on which it is built, deals with fundamentals. We have stressed fundamentals. We have gone so far in our curriculum as to make it necessary for the members of the fundamental classes, preclinical members, to be present on a ward round. We have abolished the didactic teaching in the third year. Our students enter the wards. After the completion of the second year they are turned loose, so to speak, to learn their medicine first hand. Dean Porter chose a junior department member to be chairman of the curriculum committee. Then he chose young bloods to compose that curriculum committee. I think there would be considerable difficulty if the heads of departments, for instance, composed the curriculum committee.

## RADIO BROADCASTS

The American Medical Association broadcasts over WEAf, the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen, your health!" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

**Red Network**—The stations on the Red network of the National Broadcasting Company are WEAf, WEEL, WTIC, WJAR, WTAR, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF.

**Pacific Network**—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOVO, KHQ, KFSD, KTAR.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

- April 14 Summer Camps Morris Fishbein M D
- April 21 Health and the School Morris Fishbein M D
- April 28 Infant Care W W Bauer M D

## BROADCASTS FROM THE KANSAS CITY SESSION

Special radio programs will be broadcast from Kansas City during the week of the annual session.

### NATIONAL BROADCASTING COMPANY

The following programs will be delivered over a network of the National Broadcasting Company.

An interview about the Scientific Exhibit with Dr. Morris Fishbein. Fifteen minutes. Date to be announced.

Address by Dr. James Tate Mason, President of the American Medical Association. Fifteen minutes. Date to be announced.

May 12, 4 p m. The regular dramatized program "Your Health" (originating in Chicago), based on papers or exhibits presented at the convention. Thirty minutes.

### COLUMBIA BROADCASTING SYSTEM

The following programs will be broadcast over a network of the Columbia Broadcasting System.

May 11, 1 30 p m. An interview with one or more distinguished foreign visitors by Dr. Morris Fishbein. Subject to be announced. Fifteen minutes.

May 15, 2 p m. A news broadcast outlining the main events of the convention. Dr. W W Bauer. Fifteen minutes.

A dramatized program (originating in Chicago), based on papers or exhibits presented at the convention. Thirty minutes.

The hour given is central standard time, eastern standard time is one hour later, mountain time one hour earlier, and Pacific time two hours earlier. Where date and time are not specified, an announcement will be made later.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

## ALABAMA

**State Medical Meeting at Montgomery**—The Medical Association of the State of Alabama will hold its annual meeting in Montgomery, April 21-23, with headquarters at the Jefferson Davis Hotel and under the presidency of Dr. Charles A. Thigpen, Montgomery. The program will be presented by the following:

- Dr. Edward W. Peterson, New York: Appendicitis in Infancy and the Younger Group of Children.
- Dr. Fred W. Rankin, Lexington, Ky.: Modern Management of Organic Lesions of the Colon and Rectum.
- Dr. Edgar Burns, New Orleans: Surgery of the Prostate.
- Dr. Carl H. Davis, Milwaukee: motion picture demonstrations: Normal Labor and Use of Forceps.
- Dr. Willis C. Campbell, Memphis: Physiologic Principles Applied to the Treatment of Fractures.
- Dr. Andrew B. Rivers, Rochester, Minn.: Etiology, Pathology and Treatment of Peptic Ulcer.
- Dr. Walter E. Dandy, Baltimore: Diagnosis and Treatment of Brain Tumors.
- Dr. John H. Musser, New Orleans: Abdominal Pain Due to Extra Abdominal Conditions.
- Dr. Edward C. Flett, Memphis: Ocular Tuberculosis.
- Dr. William D. Haggard, Nashville: Recent Developments in the Study and Surgery of Gout.

Dr. William D. Partlow, superintendent of the Alabama Insane Hospitals, Tuscaloosa, will deliver the Jerome Cochran Lecture on "The Debt the World Ows to Medical Science." A public meeting will be held Wednesday evening. Dr. Thomas Parran, Jr., surgeon general, U S Public Health Service, will discuss "The Next Achievement in Public Health," and Dr. William W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, "Popular Beliefs That Are Not So."

## CALIFORNIA

**Department of Public Health Issues Handbook**—Under the editorship of Dr. Paul J. Hanzlik, the Department of Public Health of the City and County of San Francisco has issued a handbook of "Accepted Remedies, Symptoms and Treatment of Poisoning, Diagnostic Procedures and Miscellaneous Information, to be used by physicians and others employed in city

and county institutions. The remedies recommended are limited largely to those in the U. S. Pharmacopeia, National Formulary, New and Nonofficial Remedies and to accepted dental remedies. It is anticipated that these limitations will do much to lower the drug bills of the institutions concerned.

**Medicodental Meeting**—A joint session of the Los Angeles County Medical Association and the Los Angeles County Dental Society will be held at the headquarters of the medical society, Los Angeles, April 14. The following speakers will present the program:

David W. McLean, D.D.S., Mechanical Causes of Dental Pathology  
Dr. Lewis Gunther, General Concepts of Calcium Metabolism  
Dr. John Martin Askey, Misconceptions of Calcium Metabolism  
Dr. Samuel J. Glass, Endocrine Aspects of Some Dental Abnormalities  
Julio Endelman, D.D.S., A Plea for a More Thorough Medicodental Cooperation

**Society News**—Dr. Charles F. McCuskey, Los Angeles, read a paper entitled "Anesthesia and Anesthetics" before the Santa Barbara County Medical Society, February 10. At a meeting of the Alameda County Medical Association, Oakland, March 16, speakers included Drs. Judith Ahlem on common factors in minor psychoses and William F. Holcomb, osteomyelitis. Dr. Ernest M. Hall, Los Angeles, discussed "The Adrenals—A Clinical and Pathological Study" before the San Diego County Medical Society, March 10. The San Francisco County Medical Society will be addressed April 14 by Drs. William J. Kerr on "Geographic Distribution of Endemic Goiter in the United States," and Jay Marion Read, "Relationship of Exophthalmic Goiter to Endemic Goiter."

### CONNECTICUT

**Memorial Services for Dr. Mendel**—Services commemorating the late Lafayette Benedict Mendel, Ph.D., Sterling professor of physiologic chemistry, Yale University School of Medicine, New Haven, will be held at Strathcona Hall, Yale University, April 16. Speakers will include James Rowland Angell, LL.D., president of the university, who will preside, Russell Henry Chittenden, Sc.D., New Haven, Frederic Collin Walcott, D.Sc., Norfolk, and Dr. Phoebe Aaron T. Levene, New York.

### FLORIDA

**Personal**—Dr. Julius C. Davis, Quincy, has been appointed a member of the state board of medical examiners, succeeding Dr. Eugene G. Peek, Ocala.

**Radio Symposium on Medical Economics**—The committee on public relations of the Florida Medical Association began a weekly radio program of lectures on medical economics, March 1. The following physicians are participating: John S. Tuberville, Century; George C. Tillman, Gainesville; Homer L. Pearson Jr., Miami; Orion O. Feaster, St. Petersburg; Calvin D. Christ, Orlando; Herbert L. Brvans, Pensacola; Thomas H. Bates, Lake City; William H. Spiers, Orlando; Edward Jelks, Jacksonville; Thomas M. Palmer, Jacksonville; and James Ralston Wells, Daytona Beach.

### GEORGIA

**Georgia University News**—Dr. George Lombard Kelly, Augusta, dean, University of Georgia School of Medicine, was appointed superintendent of the University Hospital by the board of trustees at a meeting, March 12, effective April 1. Carl G. Hartman, Ph.D., Baltimore, addressed the Louis A. Dugas Journal Club of the university, March 16, on "The Physiology of Menstruation." Construction of a new laboratory building on the campus of the medical school at a cost of \$75,000 will begin in the near future.

**State Medical Meeting at Savannah, April 21-24**—The Medical Association of Georgia will convene in Savannah for its annual session April 21-24, under the presidency of Dr. James E. Paulin, Atlanta, with headquarters at the DeSoto Hotel. A public meeting Wednesday evening will be addressed by Drs. Arthur M. Shipley, Baltimore, on "The Problem of the Diaphragm," James S. McLester, Birmingham, Ala., President, American Medical Association, "Influence of the Present Day Depression upon the Nutritive State of the American People," and Jonathan C. Meakins, Montreal, "Management of the Chronic Heart." Dr. William Bosworth Castle, associate professor of medicine, Harvard Medical School, Boston, will deliver the Abner Wellborn Calhoun Lecture, Wednesday noon, on "Fundamental Aspects of the Diagnosis and Treatment of Anemia." A symposium on the thyroid and parathyroid problems will be presented by Drs. Thomas C. Davison, James Gaston Gay, and Benjamin Hill Clifton, all of Atlanta,

and John Reid Broderick, Savannah. In addition, the following physicians will speak, among others:

William Edward Storey, Columbus, The Dilution and Concentration Tests of Kidney Function  
Joseph D. Gray, Augusta, Primary Bronchial Carcinoma  
Hal M. Davison, Atlanta, Chronic Arthritis and Fibrositis  
Millard E. Winchester, Brunswick, Use of Atabrine in the Control and Treatment of Malaria  
James R. McCord, Atlanta, Conservative Obstetrics Will Materially Lower the Mortality Rate in Eclampsia  
Thomas F. Abercrombie, Atlanta, Public Health Problems in Georgia  
Howard J. Morrison, Savannah, Antitoxin Treatment of Meningococcal Infections and Meningitis  
William A. Smith, Atlanta, Treatment of Myasthenia Gravis  
John Calvin Weaver, Atlanta, Hemorrhages of the Brain: Their Differentiation and Treatment

The annual banquet will be Thursday evening with Dr. Cornelius F. Holton, Savannah, as toastmaster. Entertainment will include golf, fishing, and a trap shooting tournament. The woman's auxiliary will hold its annual meeting at the Hotel Savannah, April 21-23.

### ILLINOIS

**Society News**—Dr. Paul C. Schnoebelen, St. Louis, addressed the Madison County Medical Society in Highland, March 6, on bone tumors, and Dr. Leith H. Stocumb, St. Louis, rectal diseases and their treatment. Dr. Roland M. Klemme, St. Louis, addressed the Vermilion County Medical Society, March 3, on "Traumatic Injuries of the Central Nervous System and Their Emergency Treatment." Dr. John A. Wolfer, Chicago, addressed the Peoria City Medical Society, March 17, on "Carcinoma of the Rectum and Colon." At a meeting of the Kankakee County Medical Society in Kankakee, March 12, Dr. Louis W. Sauer, Evanston, discussed whooping cough.

### Chicago

**Department of Neurology Created**—Dr. Eric Oldberg, acting head of the department of surgery, University of Illinois College of Medicine, since the death of Dr. Carl A. Hedblom in 1934, has been appointed professor and head of a newly created department of neurology and neurologic surgery, effective September 1. Dr. Oldberg, who is 34 years old, graduated from Northwestern University School of Medicine in 1928.

**Society News**—At a meeting of the Chicago Surgical Society, April 3, speakers included Drs. Robert B. Malcolm on "Surgery of Salivary Glands," Graham A. Kernwein, "Effect of Starvation on Fracture Healing," and Sumner L. S. Koch, "Osteomyelitis of the Bones of the Hand." Dr. Mary G. Schroeder discussed "The Diagnosis and Treatment of Psychoneurosis" before the Chicago Council of Medical Women, April 3. The Chicago Laryngological and Otolological Society devoted its meeting, April 6, to a symposium on pathology. At a meeting of the Chicago Gynecological Society, April 17, Dr. Elmer L. Sevringhaus, Madison, Wis., will discuss "Current Endocrine Problems in Gynecology" and "A Study of Women with Irregularities of Menstruation," Carl R. Moore, Ph.D., of the University of Chicago, and Dr. Ralph E. Campbell of the University of Wisconsin Medical School, Madison, will discuss these papers.

**Lectures on Psychoanalysis**—The Institute for Psychoanalysis of Chicago announces the following lectures and seminars during its third quarter of the current year:

Mortimer Adler, Ph.D., Methods and Subject Matter of Psychology  
Drs. Franz G. Alexander and Thomas M. French, alternately, Psychoanalytic Interpretation of Psychotic Cases

For the members of the Chicago Psychoanalytic Society and the candidates of the institute only, the following is offered:

Dr. Alexander, Clinical Conferences  
Dr. Alexander, Termination of Analyses (seminar on technique)  
Dr. French, Seminar on Review of Psychoanalytic Literature

Registration for the courses should be made in advance. Fees vary for the courses. The first session began April 4, but new courses are scheduled to begin in subsequent weeks, extending into June. Address: The Institute for Psychoanalysis, 43 East Ohio Street, Chicago.

### IOWA

**Society News**—Dr. Maurice C. Howard, Omaha, gave a lecture on "Cardiac Irregularities" before the Shelby County Medical Society, February 11, in Harlan. The Woodbury County Medical Society was addressed in Sioux City, February 12, by Dr. Robert S. Dinsmore Jr., Cleveland, on "Practical Points in the Treatment of Gallbladder Disease." Dr. Carl H. Gellenthien, Valmora, N.M., addressed a special meeting of the Des Moines Academy of Medicine and Polk County Medical Society, March 10, on "Practical Methods of

**Sanatorium Treatment of Pulmonary Tuberculosis**—A symposium on obstetrics was presented at the meeting in Des Moines, February 25, Drs Walter E Baker, Floyd W Rice, Audra D James and William O Purdy were the speakers.—The program of the Linn County Medical Society, April 10, was a clinic in psychiatry given by Dr Andrew H Woods, medical director of the Iowa State Psychopathic Hospital, Iowa City, and his staff

### KANSAS

**Course in Neuropsychiatry**—The medical staff of the Menninger Clinic will conduct its second annual graduate course in neuropsychiatry in general practice, April 20-25, at the Menninger Clinic, Topeka. Guest speakers will be Drs Israel S Wechsler, professor of clinical neurology, Columbia University, New York, James W Kernohan, associate professor of pathology, University of Minnesota School of Medicine, Rochester, Frederick P Moersch, Rochester, Minn, and Harry Wilkins, associate professor of surgery, University of Oklahoma School of Medicine, Oklahoma City

### MARYLAND

**Society News**—The Baltimore City Medical Society held a joint session with the Baltimore City Dental Society, March 20, a medicodental symposium was presented by Dr Sydney R Miller, George M Anderson, DDS and B Lucian Brun, DDS.—The Baltimore County Medical Society was addressed at the University Hospital, Baltimore March 18, by Drs Allen F Voshell and Edward A Looper on physical therapy and cancer of the larynx, respectively

**Personal**—Dr John H Janney Jr, Annapolis, since 1931 health officer of Anne Arundel County, sailed from New York for Rumania, April 8. As a member of the Rockefeller Foundation Dr Janney was placed in charge of the unit in Anne Arundel County when a model health department was established there under the auspices of the foundation and the Johns Hopkins University School of Hygiene and Public Health, cooperating with the state and county health departments. The university and the foundation withdrew from the experiment in 1934, but Dr Janney remained as health officer

### MASSACHUSETTS

**Personal**—Dr Walter B Cannon Boston, has been elected a member of the board of scientific directors of the Rockefeller Institute for Medical Research New York.—Dr Frank Fremont-Smith resigned as assistant professor of neuropathology at Harvard Medical School, February 1

### MICHIGAN

**The Huber Memorial Volume**—A memorial volume to Dr Gotthelf Carl Huber, who at the time of his death in 1934 was dean of the University of Michigan Graduate School of Medicine, is now being prepared by a committee under the direction of the dean of the medical school and the board of directors of the Alumni Association. The volume will contain scientific articles by Dr Huber's students and co-workers an account of his life and a complete bibliography. It will appear as a regular issue of the *Journal of Comparative Neurology* and will contain about 700 pages and 200 illustrations. Those who wish to participate in paying for this production may do so by sending a check to Dr John T Hodgen, Blodgett Medical Building East Grand Rapids. The names of contributors will be recorded. Those subscribing \$10 or more to the guaranty fund may secure the volume at half price

**Society News**—Dr Albert C Furstenberg, Ann Arbor, addressed the Calhoun County Medical Society, February 25 on "Acute Infections of the Throat and Soft Tissues of the Neck."—Dr Bruce H Douglas Detroit addressed the East Side Physicians' Association, February 27 on Present Day Trends in Tuberculosis.—At a meeting of the Wayne County Medical Society with the Detroit Bar Association, March 16 Albert E Meder, LL.D., Detroit discussed the legal point of view of social security legislation, and Dr Stanley W Insley the medical point of view.—The Detroit Academy of Surgery was the guest of Dr Nelson M Percy at the Augustana Hospital, Chicago, March 14.—Dr Irving McQuarrie Minneapolis, discussed "Recent Studies on Etiology and Treatment of Edema in Children" before the Detroit Pediatric Society, March 4.—Dr Frank J Sladen Detroit addressed the Oakland County Medical Society in Pontiac March 17, on arthritis

### NEVADA

**Annual Registration Due May 1**—All persons holding licenses to practice medicine in Nevada are required by law to pay annually to the treasurer of the Board of Medical Examiners, on or before May 1, a tax of \$2. Failure to do so operates to forfeit a licentiate's right to practice medicine, and his license to practice can be reinstated thereafter only on the payment of a \$10 penalty

### NEW YORK

**Institute on Vision**—The blindness prevention bureau of the New York State Department of Social Welfare sponsored an institute for the conservation of vision in cooperation with the Medical Society of the County of Westchester and local organizations at Yonkers, March 3. Physicians on the program included

Dr Angelo J Smith Yonkers Anatomy and Physiology of the Eye  
Dr Raymond E Meek New York Nutrition in Relation to the Eyes  
Dr Earl P Lisher Yonkers Relationship of Nose and Throat Infections to the Eye  
Dr Donald E Tinkess New Rochelle Errors of Refraction  
Dr James G Morrissey Yonkers Ocular Muscle Defects  
Dr Edward C Wood White Plains The Eye in Relation to General Disease  
Dr Laurence D Redway, Ossining Eye Injuries and Sympathetic Ophthalmia

**Alumni Meeting in Buffalo**—The Alumni Association of the University of Buffalo School of Medicine will present its second annual graduate clinical meeting April 18, with the following program

Dr Donald C Balfour Rochester Minn Problems Concerned in the Management of Lesions of the Stomach and Duodenum  
Dr Walter C Alvarez Rochester Minn Helpful Hints in the Diagnosis of Puzzling Types of Indigestion  
Dr Charles A Elsborg New York Localization and Diagnosis of Brain Tumors by Olfactory Tests  
Dr Nicholson J Eastman Baltimore Treatment of Asphyxial Neonatorum  
Dr Ernest E Irons Chicago Chronic Arthritis a General Disease Requiring Individualized Treatment  
Dr Philip D Wilson New York Fractures in the Region of the Elbow  
Dr Francis F Schwenker Baltimore, Immunization in the Treatment of Infectious Diseases

At the annual banquet at the Hotel Statler the speaker will be Dr Reginald Fitz, Boston, who will present "The Biography of the Famous Dr Watson of the Sherlock Holmes Stories"

**Bills Introduced**—S 1834 and A 2188 propose to grant to physicians, treating persons injured through the fault of others, liens on all rights of action, claims judgments, compromises or settlements accruing to the injured persons by reason of their injuries. S 1893, to amend the workmen's compensation act, proposes to permit an employee injured in the course of his employment to obtain at his employer's expense such dental care as may be necessary because of the industrial injury and to permit the employee to choose a dentist from a list of approved dentists to be compiled by the industrial commissioner. The bill also proposes to add three members to the industrial council, who are to be dentists. A 2175 to amend the law relating to certificates of birth, proposes that a certificate of birth shall contain a photograph of the fingerprints of the mother and the footprints of the child, the impression of which is to be taken as soon after the birth of the child as is practicable. S 1812, to supplement the pharmacy practice act proposes to prohibit the sale or other distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases without a license from the state board of pharmacy authorizing such sale or distribution. The provisions of the bill, however, are not to apply to licensed physicians. The bill further prohibits the sale of such appliances, drugs or medicinal preparations unless their containers or labels specifically identify the manufacturer and unless such goods comply with standards which may be prescribed by the division of laboratories and research in the department of health. S 1862, to amend the medical practice act, proposes to require applicants for licenses to practice medicine to be citizens of the United States. A 2248 to amend the medical practice act, proposes, in addition to the grounds now stated in the law, to authorize the revocation of the license of a physician who (1) has employed, lured, procured or induced a person not licensed to practice medicine in the state to so practice, (2) has aided and abetted in the practice of medicine a person who is not licensed to practice medicine in the state, or (3) has advertised for patronage by means of handbills posters, circulars, flamboyant signs, stereopticon slides, motion pictures, radio or magazines

## New York City

**Harvey Lectures**—The sixth Harvey Lecture of the season will be delivered by Dr Warren H Lewis, professor of physiologic anatomy at Johns Hopkins University School of Medicine, Baltimore, on "Malignant Cells." The lecture will be at the New York Academy of Medicine, April 16. Dr Ivan de Burgh Daly, professor of physiology, University of Edinburgh, Scotland, will deliver the seventh lecture, May 21, on "The Physiology of the Bronchial Vascular System."

**Society News**—Dr Joseph C Aub Boston, addressed the New York Endocrinological Society, March 25, on "Abnormalities of the Thyroid Glands."—Speakers at a meeting of the National Society for the Advancement of Gastro-Enterology at the New York Academy of Medicine, March 24, were Drs Thomas Fitz-Hugh Jr, Philadelphia, on "Acute Gonococcal Perihepatitis—A New Syndrome of Right Upper Quadrant Abdominal Pain in Young Women" Reuben J Erickson, Albany, "Tuberculosis of the Intestine", Lester R Whitaker, Boston, "Electrocholecystocausis," and Henry Baker, Boston, "Insulin Treatment in Gastro-Intestinal Diseases."

**Free Service Denied to Persons Able to Pay**—Investigation of the financial status of applicants for free service in city hospitals or in private hospitals at city expense has resulted in a saving of about \$1,000,000 to the city, Dr Sigismund S Goldwater, commissioner of hospitals, announced recently. The division of investigation found in 1935 that nearly 9 per cent of those who applied for free hospitalization in city institutions, 12 per cent in private general hospitals and 5 per cent in private special hospitals were not eligible for free care at the taxpayers' expense. Before 1935 only those who actually occupied hospital beds underwent investigation, but clinic applicants are also investigated now, with the result that in 1935 over 7 per cent were rejected as not eligible. The division of investigation made decisions on 622,299 applicants during the year, 519,136 in the city institutions.

**Hospital News**—The Queensboro Hospital, a fifty-four bed institution, was merged with the new Queens General Hospital March 1. The smaller hospital occupies part of the grounds of the new 580 bed general hospital, which was opened last October.—The Society of the New York Hospital announced February 21 that the Convalescent Home for Children, at White Plains, had been closed for an indefinite period. For several years operation of the home has resulted in a deficit of about \$50,000 a year, a sum which the society can no longer meet, it was said. It has cared for more than 22,000 children in the twenty eight years of its existence.—A new twelve story nurses' home and school is to be built immediately for St Luke's Hospital at a cost of \$1,200,000, it was announced March 5. It is designed to accommodate 300 nurses.—Dr Sigismund S Goldwater, commissioner of hospitals, recently appealed to private hospitals that receive city subsidies to take more ward patients to relieve overcrowding in the city's institutions. He pointed out that city hospitals are heavily overloaded, while wards in private hospitals are only 75 per cent occupied.

## NORTH CAROLINA

**Society News**—At the annual meeting of the Second District Medical Society in New Bern, recently, speakers included Drs Paul H Ringer, Asheville, and Louis B McBraver, Southern Pines, president and secretary, respectively, of the Medical Society of the State of North Carolina, James G Ramsay, Washington, "Ruptured Duodenal Ulcer", Elwood R Boney, Kinston, "Allergy in General Medicine," and David T Smith, Durham, "Vincent's Infections of the Lung."—Dr Karl Schaffle Asheville, addressed the Buncombe County Medical Society, March 2 on "Nervous Disorders Associated with Pulmonary Tuberculosis."—Dr Lester C Todd, Charlotte discussed allergy at a meeting of the Catawba Valley Medical Society, Lincolnton, March 10.

## OKLAHOMA

**Society News**—Drs Ray M Baljeat and Carroll M Pounders, Oklahoma City, addressed the Woods-Alfalfa County Medical Society, Alva, recently, on "Intratracheal Use of Iodized Oil in Treatment of Intractable Asthma and 'Pneumonia in Infancy and Childhood respectively."—Dr Charles F Walker, Grove, addressed the Craig County Medical Society, Vinita, April 7, on "Infections Following Labor and Salpingitis."—Drs Albert W Pigford and George R Osborne, Tulsa, addressed the Rogers County Medical Society, Claremore, April 20, on carcinoma and obstetrics, respectively.

## PENNSYLVANIA

**Personal**—Dr John Speer Donaldson, Pittsburgh, has been appointed chief surgeon of the State Hospital for Crippled Children, Elizabethtown, succeeding Dr Francis S Chambers.—Dr James S Hammers, former superintendent of the Pittsburgh City Home and Hospital, Mayview, has been appointed medical director of the Lancaster County Hospital and Hospital for Insane, Lancaster.—Dr George T Rodman, Hawley, recently celebrated the fiftieth anniversary of his medical practice.

**Society News**—Dr Charles L Brown, Philadelphia, was guest speaker at a meeting of the Schuylkill County Medical Society, Pottsville, March 11, on "Management of Congestive Heart Failure."—Dr Edward C Rosenow, Rochester, Minn, addressed the Erie County Medical Society, Erie, March 10, on "Newer Experimental and Clinical Studies on Focal Infections and Elective Localizations."—Dr William Devitt, director of Devitt's Camp for tuberculosis near Allenwood, was elected president of the Pennsylvania Tuberculosis Society at its annual meeting February 26. Dr Devitt succeeds Dr Charles Howard Marcy, Pittsburgh, who served four years.

## Philadelphia

**Hospital News**—Dr Wilbur P Rickert has been named superintendent of the Philadelphia Hospital for Mental Diseases. Two new buildings will be erected at the hospital, which is said to be overcrowded.—Dr Harry Lowenburg has been appointed pediatrician to the Philadelphia General Hospital.—Dr George R Minot, Boston, delivered the Benjamin Rush Lecture before the staff of the Pennsylvania Hospital, January 16, on "Some Aspects of Anemia and Purpura Hemorrhagica."

**County Society to Hold Graduate Institute**—The Philadelphia County Medical Society will present its first graduate institute at the Bellevue-Stratford, April 20-24. The institute will deal with cardiovascular and renal diseases, which will be discussed by fifty-three members of the faculties of the University of Pennsylvania School of Medicine and Graduate School of Medicine, Jefferson Medical College, Temple University School of Medicine and the Woman's Medical College of Pennsylvania. At the opening luncheon Dr George C Yeager, president of the county society, will preside and speakers will be Mayor S Davis Wilson, Drs William C Hunsicker, director of the Philadelphia Department of Public Health and Maxwell J Lick, Erie, president-elect of the Medical Society of the State of Pennsylvania. A banquet will be held Wednesday evening, April 22, at the Bellevue-Stratford with Drs Alexander H Colwell, Pittsburgh, president of the state society, and Frank H Lahey, Boston, as speakers. Later Dr Lahey will deliver the J Chalmers Da Costa Oration on "Management of Biliary Tract Disease" at the regular meeting of the county society.

## SOUTH CAROLINA

**State Medical Meeting**—The eighty-eighth annual session of the South Carolina Medical Association will be held in Greenville, April 21-23 with headquarters at the Poinsett Hotel. The guest speakers will be Drs George W Crile, Cleveland and William B Porter, Richmond, Va. South Carolina physicians listed on the program include:

Dr Charles R F Baker Sumter Treatment of Intestinal Obstruction by the Use of the Duodenal Tube and Suction  
Dr Roy P Finney Spartanburg Bedside Observations on the Dying  
Dr David F Adecock Columbia Blood Transfusion  
Dr Roger G Doughty Columbia Thyroid Disease  
Dr Allen Izard Josey Columbia Cardiac Pain and Its Management  
Dr James R Young Anderson Clinical Study of 2,500 Cases of Appendicitis at the Anderson County Hospital over a Thirteen Year Period  
Dr Carl B Epps Sumter The Question of Drainage in Abdominal Surgery  
Dr Hilley Rudisill Jr Charleston Facts of General Interest About X Rays and Radium  
Dr John M van de Erve Charleston Vesicular Eruptions of the Hands  
Dr Joseph H Cutchins Easley Simplified Ketogenic Diet in the Treatment of Bacillary Infection of the Urinary Tract  
Dr Joseph I Waring Charleston Prevention of Loss of Weight in the New Born  
Dr Benjamin O Whitten Clinton Psychology of Subnormal Individuals  
Dr LeGrand Guerry, Columbia A Method for Reconstruction of the Common Duct  
Dr William R Wallace Chester Screw Worm Infestation  
Dr Daniel Lesesne Smith Jr Spartanburg Treatment of Congenital Syphilis

## TENNESSEE

**Death Rates Declined in 1935**—The Tennessee Department of Health reports that the provisional death rate for 1935 was 10.6 per thousand of population as compared with 10.9 for 1934. The infant death rate declined from 74.8 per thousand live births in 1934 to 64 in 1935, a new low record for the state. The typhoid death rate was 6.5 per hundred thousand of population, compared with 7.5 in 1934. The provisional mortality rate from diphtheria was 6.5, also a reduction from the 1934 rate of 7.4. The birth rate was 18.5 per thousand of population, an increase from the 1934 rate of 18.4.

**Society News**—Drs. Carl W. Brabson, Telford, and Prentiss E. Parker, Johnson City, addressed the Washington County Medical Society, Johnson City, March 5 on "Diseases of the Stomach" and "Sympathectomy in the Treatment of Thrombo-Angitis Obliterans" respectively. At a meeting of the Campbell County Medical Society, Jellico, recently, Dr. Russell W. Lewis, Westbourne, discussed measles. Drs. Edward F. Buchner, Jr. and Franklin B. Bogart, Chattanooga, addressed the Chattanooga and Hamilton County Medical Society, March 5 on "Rate of Growth Before Birth" and "Radiation Therapy and the General Practitioner" respectively. A symposium on cancer was presented at the meeting of the Dyer Lake and Crockett Counties Medical Society, March 4 by Drs. Charles G. Andrews, Robert L. Sanders, and John L. McGehee, Memphis. Dr. Augustus H. Lancaster discussed congenital syphilis at a meeting of the Knox County Medical Society, Knoxville, March 3.

**State Medical Meeting in Memphis**—The one hundred and third annual meeting of the Tennessee State Medical Association will be held in Memphis, April 14-16. Guest speakers will be Drs. James S. McLeister, Birmingham, Ala., President, American Medical Association, Martin Hayward Post, St. Louis, who will speak on "Tuberculin Therapy in Ocular Tuberculosis," and John S. Coulter, Chicago, "Physical Therapy in Chronic Arthritis." Tennessee physicians listed on the program include:

Dr. Edward Dunbar Newell, Chattanooga, Local Anesthesia in the Reduction of Fracture.  
Dr. Jesse C. Hill, Knoxville, Afebrile Exhaustive Psychosis Following Sickness.  
Drs. William D. Anderson and Walter S. Lawrence, Memphis, An Evaluation of Radiation in Certain Diseases of the Female Pelvis.  
Dr. Edward D. Mitchell, Jr., Memphis, Symptoms of Peptic Ulcer.  
Dr. George R. Livermore, Memphis, Urinary Antiseptics.  
Dr. Henry B. Gotten, Memphis, Obesity and Malnutrition.  
Dr. William T. Pride, Memphis, Repairs of New and Old Lacerations Following Childbirth.  
Dr. Lucius E. Burch, Nashville, Cesarean Section—Indications, Contra-indications and Technique.  
Dr. William R. Cate, Nashville, Pneumonia with Special Reference to Typing and Specific Therapy.  
Dr. Wilson C. Williams, Nashville, The State Health Program.  
Dr. William E. Boyce, Flatwoods, The Chemistry of Barbituric Acid and Its Derivatives.

The Tennessee State Pediatric Association will hold its annual meeting, April 14, with Dr. Hugh McCulloch, St. Louis, as guest of honor. The women's auxiliary will also meet April 14-16.

## WISCONSIN

**Vital Statistics**—The state board of health reports that the provisional death rate for 1935 is 10.1 per thousand of population, the same as the official rate for 1934. Heart disease with a rate of 248.1 per hundred thousand and cancer with a rate of 124.7 were the leading causes of death. The rate of maternal mortality was 3.6 per thousand live births compared with a final rate of 4.2 in 1934; this is the lowest rate ever reached in Wisconsin. The infant mortality rate was 45.2 per thousand live births, also the lowest ever recorded. More deaths from automobile accidents were reported than ever before, 750 as compared with 665 for the preceding year. The tuberculosis death rate, 35.3, was the lowest that the state has ever had.

## PHILIPPINE ISLANDS

**Medical Board Appointments**—Drs. Jose M. Delgado and Cesario Santa Ana, Manila, have been appointed members of the Board of Medical Examiners of the Philippine Islands and Dr. Rufino Abriol, Manila, chairman.

## HAWAII

**Personal**—Visitors to Honolulu recently included Drs. George E. Brewer, emeritus professor of surgery, Columbia University College of Physicians and Surgeons, New York, and William A. Coventry, Duluth, Minn., past president of the Minnesota State Medical Association.

## GENERAL

**Meeting of Committee on Maternal Welfare**—The American Committee on Maternal Welfare will hold its annual meeting at the Hyde Park Hotel, Thirty-Sixth and Broadway, in Kansas City, May 13, under the presidency of Dr. Fred L. Adair, Chicago; the secretary is Dr. James R. McCord, 50 Armstrong Street, Atlanta. Reservations for luncheon may be made through Dr. LeRoy A. Calkins, the University of Kansas, Kansas City, Kan. Members and others interested are invited.

**Meeting of American Heart Association**—The twelfth annual meeting of the American Heart Association will be at the Hotel Phillips, Kansas City, May 12. Speakers will include the following physicians:

William B. Kountz, St. Louis, Studies on the Revived Human Heart.  
Louis N. Katz, David B. Witt, and Miss E. Lindner, Chicago, The Dynamic Effect of Acute Experimental Poisoning of the Heart with Diphtheria Toxin.  
Howard B. Sprague, Boston, Differential Diagnosis of Congestive Heart Failure and Constrictive Pericarditis.  
William J. Kerr and Franklin J. Underwood, San Francisco, Hemiconstriction of Vascular System Associated with Cerebral Disease.  
Irvine H. Page, New York, Anterior Nerve Root Section and Sympathetic Section in the Treatment of Hypertension.  
Wallace M. Yater, Washington, D. C., Thorotrast Arteriography in Vascular Diseases of the Extremities.

**Radium Society Meeting**—The annual meeting of the American Radium Society will be held at the Hotel Kansas City, Kansas City, Mo., May 11-12. Dr. Curtis F. Burnam, Baltimore, will deliver the Janeway Lecture at the annual banquet Monday evening, May 11, at the University Club. Dr. Douglas Quick, New York, chairman of the Janeway Lecture Committee of the society, will present the Janeway Medal to Dr. Burnam and to the previous annual lecturers, Drs. James Ewing and Francis Carter Wood, New York, and George E. Pfahler, Philadelphia. Dr. Zoe Allison Johnston, Pittsburgh, will be installed as president at this meeting. Dr. George W. Grier, Pittsburgh, is the present president and Dr. Edward H. Skinner, Kansas City, secretary.

**Health Officers' Conference**—The annual Conference of State and Territorial Health Officers with the U. S. Public Health Service will be held in Washington, D. C., April 13-14. The program will include a symposium on the control of syphilis with the following speakers: Drs. Raymond A. Vonderlehr of the public health service, Joseph Earle Moore, Baltimore, Dudley C. Smith, University, Va., Arthur J. Caslesman, Trenton, N. J., John H. Stokes, Philadelphia, and Nels A. Nelson, Boston. There will also be a symposium on industrial hygiene and the second day will be devoted to discussion of policies and procedures in connection with administration of the public health phases of the social security act. The Children's Bureau of the Department of Labor will hold a similar conference with the health officers April 15-16.

**Meeting of Proctologists**—The American Proctologic Society will hold its annual meeting at the Hotel Kansas City, Kansas City, Mo., May 11-12. There will be symposiums on "Diverticulosis and Diverticulitis," "Causes of High Rectal and Low Back Pain" and "Pilonidal Sinus." The following speakers will present formal papers:

Dr. Collier F. Martin, Philadelphia, Variety and Distribution of Gross Lesions in Lymphopathia Venerea.  
Dr. Dudley A. Smith, San Francisco, Fistula in Ano.  
Dr. Louis A. Buie, Rochester, Minn., Anterior Lymphatic Abscess.  
Dr. Louis J. Hirschman, Detroit, Drainage in Certain Anorectal Operations.  
Dr. Harry E. Bacon, Philadelphia, Pruritus Ani.  
Dr. Frederick B. Bowman, Hamilton, Ont., Injection Treatment of Prolapse of the Rectum.  
Dr. Frank H. Murray, Chester, Pa., Association of the Proctologic and Urinary Tracts.

**Bequests and Donations**—The following bequests and donations have recently been announced:

Protestant Episcopal and Frankford hospitals, Philadelphia, \$5,000 each by the will of Bertha S. Wilbraham.  
Abington Memorial Hospital, Abington, Pa., and Children's Hospital, Philadelphia, \$5,000 each by the will of Sara R. Halliwell, Philadelphia.  
Lankenau Hospital, Philadelphia, awarded \$9,250 held in trust for eighteen years from the estate of Mrs. Louis A. Scharda.  
Jewish Hospital, Philadelphia, \$5,000; Mount Sinai Hospital, Philadelphia, \$2,000; Jewish Consumptives' Home, Denver, \$2,000; Eagleville Sanatorium, Eagleville, Pa., \$1,000 by the will of Meyer Hoffman, Philadelphia.  
Germantown Hospital, Philadelphia, \$500 by the will of Mrs. Eliza Beth B. Wistar Warner.  
Montefiore and Mount Sinai Hospitals, New York, \$5,000 each by the will of the late Marco Fleishman.  
Presbyterian Hospital, Philadelphia, \$10,000 from the estate of Henry R. Mulford, a policeman, \$5,000 by the will of Clara S. Stevenor.  
The following New York hospitals received bequests in the will of the late Charles Klingenstein: Fire Vets' Hospital, Lenox Hill, Lehigh and Neurological Institute, \$1,000 each; Beth Israel, \$2,000; Montefiore, \$5,000; Mount Sinai, \$5,000.

**Low Mortality Record**—A new low mortality rate, 8.4 per thousand of population, was recorded among the 17,000,000 policyholders of the Metropolitan Life Insurance Company in 1935, according to its *Statistical Bulletin*. New low rates were registered for typhoid, tuberculosis, diarrheal conditions, chronic nephritis and puerperal diseases, burns and drowning. The rate for typhoid was 1.1 per hundred thousand, tuberculosis, 55.6 per hundred thousand, marking a reduction of 6.4 per cent from the previous low point of 59.4 of 1934. The rate for diarrheal complaints was 8.1 per hundred thousand and the rate for puerperal diseases, 8.7. Rates for deaths from accidental burns and drowning were 3.2 and 4.9, respectively. Declines were also noted for cancer, which had a rate of 95.5, diabetes, 24.2, heart disease, 157.4, suicides, 9.1, appendicitis, 11.4, and automobile accidents, 20.3. The rate for deaths from alcoholism was the lowest for any year since 1921, 2 per hundred thousand.

**Study of Suicide**—The Committee for the Study of Suicide, recently organized in New York, has outlined plans for a comprehensive study. Intramural studies of persons inclined to suicide will be made in selected hospitals for mental disease, these will include constitutional, neurologic, psychiatric and psychoanalytic investigations, with special reference to therapy and prevention. Similar studies of ambulatory cases will be made in outpatient clinics, these studies will be primarily therapeutic. Social studies will be undertaken through follow up of attempts at suicide, with investigations of social background and history and recommendation of psychiatric or psychoanalytic treatment in agencies available to the committee. Ethnologic studies consisting of investigations of suicide among primitive races are planned. Dr Henry E. Sigerist, professor of history of medicine, Johns Hopkins University of Medicine, Baltimore, and Edward Sapir, Ph.D., Sterling professor of anthropology and linguistics, Yale University, New Haven, Conn., have been made consultant members of the committee to advise in the parts of the work that touch their fields. Executive offices of the committee are at Room 1404, the Medical Arts Center, 57 West Fifty-Seventh Street, New York. Dr Gregory Zilboorg is secretary and director of research.

**Association for Study and Control of Rheumatic Diseases**—The American Association for the Study and Control of Rheumatic Diseases will meet at the Phillips Hotel, Kansas City, Mo., at 9 o'clock and again at 2 o'clock, May 11, under the presidency of Dr Russell L. Haden, Cleveland, the secretary is Dr Loring T. Swann, 372 Marlboro Street, Boston. The following physicians will present an educational program on the differential diagnosis of diseases of joints:

Russell Haden, Cleveland. Clinical grouping and diagnostic approach to the patient with joint conditions.  
Edwin P. Jordan, Chicago. Differential diagnosis of joint diseases from the standpoint of pathology.  
Ralph H. Boots, New York. The essential features in differential diagnosis of atrophic and hypertrophic arthritis.  
Joseph L. Miller, Chicago. Differential diagnosis between Strumpell Marie disease and osteoarthritis of the spine.  
Stafford L. Warren, Rochester, N. Y. Differential diagnostic points of gonorrheal arthritis.  
Frank D. Dickson, Kansas City. Differential diagnostic points of tuberculous arthritis especially tuberculous polyarthritis.  
Ralph A. Kinsella, St. Louis. Differential diagnostic points of rheumatic fever.  
Philip S. Hench, Rochester, Minn. Differential diagnostic facts about gout, distinguishing it from other joint diseases.  
Willis C. Campbell, Memphis, Tenn. Differential diagnosis of traumatic arthritis.  
Charles H. Slocumb, Rochester, Minn. Differential diagnosis of fibrositis.  
William J. Kerr, San Francisco. Differential diagnostic points of constitutional conditions mistaken for arthritis, which produce skeletal aches and pains.

**Medical Bills in Congress—Change in Status** H. R. 12098 has been reported to the House, making appropriations for the Departments of State and Justice and for the Judiciary, and for the Departments of Commerce and Labor, for the fiscal year ending June 30, 1937. For the Children's Bureau, Department of Labor, the following appropriations are proposed: For grants to enable each state to extend and improve services for promoting the health of mothers and children, \$2,820,000, for grants to states to extend and improve services for crippled children, \$2,150,000, for grants to states for the care of homeless or neglected children, \$1,200,000. **Bills Introduced** H. J. Res. 555, introduced by Representative Mapes, Michigan, proposes to create a Joint Committee on the Reorganization of the Administrative Branch of the Government. H. R. 11661, introduced by Representative Lee, Oklahoma, proposes to provide federal service medals of honor to civilian federal employees who have made outstanding contributions to the advancement of scientific knowledge or the application of its truths in a practical way for the welfare of the human race, or who have rendered conspicuous service to humanity at the

voluntary risk of life or health over and above the ordinary risks of duty. S. 4390, introduced by Senator Sheppard, Texas, proposes to provide that appointments to the Medical Administrative Corps shall be restricted to pharmacists who are graduates of recognized schools or colleges of pharmacy requiring four years of instruction for graduation, and provides that the number of such pharmacists in the corps shall not exceed sixteen.

**Society News**—At the annual meeting of the Southern Psychiatric Association in New Orleans, February 22-23, Dr George P. Sprague, Lexington, Ky., was chosen president elect, and Dr William D. Partlow, Tuscaloosa, Ala., was installed as president. Dr Charles S. Holbrook, New Orleans, was elected vice president, and Dr Newdigate M. Owensby, Atlanta, was reelected secretary. Guest speakers at the meeting included Drs John H. Musser, New Orleans, Lloyd J. Thompson, New Haven, Milus K. Bailey, Atlanta, William E. Gardner, Louisville, Arthur J. Schwenkenberg, Dallas, Texas, Frederick L. Fenn, New Orleans, and Frank R. Gomila, commissioner of public safety, New Orleans. Dr Robert B. Greenough, Boston, was elected president of the American Society for the Control of Cancer at the recent annual meeting in New York. Dr Edmund B. Wilson, New York, is vice president and Dr Frank E. Adair, New York, secretary. Dr James Ewing, New York, was named chairman of the board. The Eugenics Research Association will meet at the American Museum of Natural History, New York, June 6. Dr Fred W. Rankin, Lexington, Ky., was chosen president-elect of the Southeastern Surgical Congress at the recent session in New Orleans, and Dr Benjamin T. Beasley, Atlanta, director general of the congress, was named secretary-treasurer. The next annual meeting will be held in Louisville, Ky. Dr Ray Lyman Wilbur, Stanford University, Calif., has been chosen president of the American Social Hygiene Association, succeeding Dr Edward L. Keyes, New York, who resigned after twelve years' service. The Association for the Study of Allergy will hold its annual meeting at the Baltimore Hotel, Kansas City, Mo., May 11-12. Dr Morris Murray Peshkin, New York, is president of the association and Dr Warren T. Vaughan, Richmond, Va., secretary.

## CANADA

**University Appointments**—Dr Charles B. Weld of the department of physiology at the University of Toronto Faculty of Medicine has been appointed professor of physiology at Dalhousie University Faculty of Medicine, Halifax, N. S. He succeeds Dr Ernest W. H. Cruickshank, who resigned in December 1935. Dr Cecil Percy Martin, chief demonstrator in anatomy and university anatomist at Trinity College, Dublin University, has been appointed Robert Reford professor of anatomy at McGill University Faculty of Medicine. Dr Martin succeeds Dr Samuel E. Whitnall, who resigned in 1934 to accept the chair of anatomy at Bristol University.

**McGill Reorganizes Curriculum**—McGill University, Montreal, announces the reorganization of its medical curriculum into a course of five years including internship. The new plan, which goes into effect in September, will replace the present undergraduate course, now spread over five academic years of seven and a half months each, by a course covering four years of nine months each. The fifth year may be spent in an internship in an approved hospital or in further medical study at McGill or at another medical school approved by it. It is expected that in most cases the intern year will be chosen, but those who choose further study will have several alternatives. Among these is the opportunity for those who wish to obtain British qualifications to spend the fifth year in a British hospital school preparing for examinations by the British licensing bodies. The minimum requirement for entrance to the medical course will remain the same, three years in a college or faculty of arts and science.

**Personal**—Dr John T. Phair, Toronto, has been appointed chief medical officer of health of Ontario; he will continue to serve as director of the division of maternal and child hygiene. Dr John G. Fitzgerald, director of the School of Hygiene and of Connaught Laboratories, University of Toronto, has been appointed a member of the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations. Dr Morris W. Thomas, Victoria, B. C., has been appointed executive secretary of the British Columbia Medical Council and British Columbia Medical Association. The Royal Society of Canada presented a gold medal to Dr James B. Collip, professor of biologic chemistry, McGill University Faculty of Medicine, Montreal, at a meeting in Ottawa, February 14, in recognition of his achievements in

science—Dr David S Hoig, medical superintendent of the Oshawa General Hospital, Oshawa, was guest of honor at a dinner given by the hospital trustees in January celebrating his twenty-fifth anniversary in that position and his fifty-fifth year as a practitioner in the community

## FOREIGN

**Congress on Light**—The third International Congress on Light will be held in Wiesbaden, Germany, September 1-7 under the presidency of Dr W Friedrich of the University of Berlin. Subjects for discussion will include the entire field of the biology of light, biophysics and the therapy of light. Information may be obtained from the secretary general, Dr H Schreiber, Berlin N W 7, Robert Koch Platz 1

**Convicted for Sale of Inaccurate Thermometers**—The U S Consul at Leipzig, Germany, David H Buftum, recently reported to the U S Department of Commerce that the manager of a Thuringia glass firm had been convicted of selling 3,000 inexact fever thermometers to Italy. The instruments had been rejected by examining authorities as not in compliance with regulations. Sentence was said to be four months' imprisonment. During the trial it was brought out that the defendant had been suspected in 1933 of selling nonapproved thermometers to foreign countries.

**Congress on Rheumatism**—The fifth International Congress on Rheumatism will be held in Lund, Sweden, September 3-5, and in Stockholm, September 7-8, under the presidency of Dr Sven Ingvar, Lund. Subjects for discussion will be allergy in rheumatic diseases, reading of roentgenograms in arthritis, nature of myalgia, and of the orthopedist in rheumatic diseases and housing conditions in relation to rheumatic diseases. American physicians listed on the program include Drs Ralph Pemberton, Philadelphia, Alvin F Coburn and Homer F Swift, New York, and Loring T Swann, Boston. The secretary of the congress is Prof G Kahlmeter, Birgerjarlsgatan 36, Stockholm.

**Congress on Microbiology**—The second International Congress for Microbiology will be held in London, July 25 to August 1, with headquarters at University College. The president of the executive committee is Prof John C G Ledingham and the general secretary Dr Ralph T St John Brooks, both of Lister Institute, London. All persons interested in microbiology may become members of the congress on payment of £1 sterling or \$5. Prospective members are urged to register early. A preliminary program may be obtained from the general secretary, whose address is Lister Institute, Chelsea Bridge Road, London, S W 1. Dr Karl Landsteiner, New York, is president of the American committee and Malcolm H Soule, Sc D, University of Michigan, Ann Arbor, secretary.

## Deaths in Other Countries

Arnold Netter, formerly professor of medicine at the University of Paris and the University of Strasbourg, died in Paris, March 1, aged 81.—Sir Charles Ballance, British surgeon, author of works on surgery of the brain, died in London in February, aged 79.

## Government Services

### U S Public Health Service

Drs Edwin H Carnes and Franklin J Halpin have been promoted and commissioned as surgeons in the regular corps of the public health service, and Drs Gregory J Van Beeck, Edward C Ernst and Peter J Gorman, as senior surgeons.

### Orthopedic Mechanic Wanted for Canal Service

A vacancy exists in the position of orthopedic mechanic in the Panama Canal service on the Isthmus. Applicants must be American citizens not more than 45 years old, in good health and physically sound. The duties of the position are to perform work of journeyman grade in mechanical orthopedics, to supervise one or two orthopedic mechanics helpers and to perform related work as assigned. Minimum qualifications include common school education, at least three years successful experience, working knowledge of standard practices of the trade, ability to perform difficult orthopedic work, skill in use of tools and equipment, ability to work from rough sketches and oral instructions, manual dexterity and ingenuity. Application blanks may be obtained from the Chief of Office, The Panama Canal, Washington, D C.

### The Problem of Eugenics

Delivering the annual Galton lecture to the Eugenics Society, Mr Julian Huxley urged that a new outlook on the scope and method of eugenics was needed. Apart from a few immediate palliative measures, such as sterilization of certain types of defectives and reduction of the differential birth rate of different classes, the main task of eugenics should be the study of the existing social system with a view to transforming it into one favorable to later measures of selective breeding. Social environment should be taken into account to a much greater extent by eugenicists. Its effects were so powerful that they easily masked hereditary effects. For instance, the average stature, physique and intelligence of the lower economic strata in Britain were lower than those of the upper. This had often been put down by eugenicists to innate inferiority. But until they had done something to equalize environment between the classes there was no scientific proof. Indeed it was practically certain that much of the difference was due to environment. The same applied with even greater force to differences in intelligence and achievement between races and peoples at different cultural levels.

Eugenicists had assumed that qualities making for success in the existing social system were eugenically desirable. This was largely mere unconscious bias. The time had now come to look at the matter on a broader basis. One way was to plan measures suited to the present social environment. Its economic structure implied that society should breed for docility in the many and for initiative and brains in the few. Its nationalist structure implied that it must consider mere quantity of population as against quality more seriously than if the risks of war and the need for military man power were reduced. Prospects of eugenic advance were thus, at best, extremely limited. Or it could plan for some remote ideal type of society. If so, it must face the fact that for a long time to come many of the genetically best types in intelligence and sensitiveness would be social misfits.

The course which scientifically and practically was the best was to attempt to transform both environment and inheritance more or less simultaneously. The equalization of social environment for different classes by upward leveling must be encouraged, for only thus could the innately superior and inferior types be picked out with certainty. Internationalism must be encouraged, otherwise there would be an obsession of the need of quantity as against quality. Society above all must avoid being dysgenic. As R A Fisher had shown, factors at present making for rise in the social scale tended to become coupled with those making for low fertility. An attempt must be made to achieve a society in which the qualities making for success were of greater value for the evolutionary progress of man than in the present system. Cooperative and altruistic tendencies and those conducive toward greater awareness and sensitivity now usually handicapped a man. They should be not only social assets but eugenic aims.

One serious danger existed. If there was one thing which modern eugenics had demonstrated it was that unfavorable mutations were much more common than favorable—that the hereditary constitution had a tendency to debase itself. In wild species this tendency was kept in check and the opposite, though weaker, tendency encouraged by natural selection, in domesticated species by artificial selection. In civilized communities the tendency to degeneration was not being checked. If nothing was done, the innate qualities of our species would slowly deteriorate by the automatic accumulation of harmful

mutations. This would occur even if civilization did not collapse through war. Active selection in the opposite direction was the only remedy. But with our present type of social system nothing but palliative tinkering was possible. A change of moral outlook and social system that would encourage eugenic reproduction was needed.

#### Research with Regard to Malarial Mosquitoes

Mr H. S. Leeson and Mr J. D. Gillett, members of the staff of the Entomological Department on the London School of Hygiene and Tropical Medicine, have left for southern Rhodesia to continue an investigation begun by the former into the life history of malarial mosquitoes. The investigation will cover the whole of Central Africa from southern Rhodesia to the Sudan. The aim is to scrutinize the two mosquitoes chiefly responsible for the carrying of malaria, to see whether they are everywhere identical and are not subdivided. Studies in Europe have shown the importance in the prevention of malaria of examining with microscopic care insects which appeared to be a simple species. They have shown that there are no fewer than six races of *Anopheles maculipennis*, that their breeding places and habits are different, and that some like brackish water, some fresh water, some warm water and some cold water and keep to the north of Europe. Some sleep at peace with all mankind during the winter, either in cold attics or in cattle sheds. Others are restive, haunt the homes of men, continue to feed during the winter and are responsible for the spread of malaria in several parts of Europe, particularly the Netherlands. In Asia similar knowledge has led to great advances in the prevention of malaria. For example, if a dangerous mosquito liked sunshine it was sometimes possible to blot it out merely by growing a hedge or jungle over its breeding place and so excluding the sunlight. In other places minute chemical changes in the water had driven out dangerous species of mosquito and freed large populations from malaria, from which they had suffered for years. The research work in Africa aims at close cooperation with agriculture and forestry. At present water remains in swamps after heavy rains, and those become very malarial. It is believed that many of these swamps could be converted from dangerous areas into reservoirs, which would assist the natives to tide over the dry season and to grow crops never grown before.

#### Clinical Application of Staphylococcus Anatoxin

The question as to whether staphylococcus anatoxin can be employed in certain forms of infection due to staphylococci is being actively debated here. The anatoxin is prepared as suggested by Prof. G. Ramon of the Pasteur Institute by the simultaneous action of a minute amount of solution of formaldehyde and a moderate degree of heat, on a bouillon culture of staphylococci previously filtered so that the filtrate contains no living organism.

An important paper by Professor Ramon and his co-workers on the use of the anatoxin, which appeared in the *Presse medicale*, February 1, advocates the injection of the anatoxin in such surface lesions due to staphylococci as furuncles, sycoes and acne. The details of the use of the anatoxin are given in this paper. The local reactions are slight, and general reactions were only febrile and never more than of twenty-four hours' duration. Two hundred cases of furunculosis were observed over a period sufficiently long to justify some conclusions. Of the 200 cases, 131 have either been cured or greatly improved. In only seven of the 131 were recurrences noted. The results of the treatment of sycoes, eczema, axillary adenitis, paronychia and acne have been equally satisfactory. In all about 500 patients have received the injections, 300 at the

Pasteur Institute and 200 by physicians throughout France, all of whom have warmly endorsed this new therapeutic method.

In a second paper (*Presse medicale* of Feb. 19, 1936) Ramon and his co-workers take up the question of the antistaphylococcal immunity produced by the specific anatoxin in patients suffering from staphylococcal infections. The anatoxin results in the formation of a specific antitoxin, which must attain a certain level in the blood in order to combat the staphylococcal infection. In the second paper the indications, injections to be given as preliminary tests of hypersensibility and the doses for treatment purposes are cited in detail.

That Ramon's warning to test the sensitivity of the patient before beginning the treatment was timely is well shown by a case reported by Duvoir and his colleagues before the *Societe medicale des hopitaux* of Paris, February 28. A woman, who was given a first injection of 0.5 cc of the anatoxin for an axillary adenitis December 13 in the outpatient department of the Hôpital St. Louis, was one of a number who had been injected the same day, none of whom reported any serious reaction. Toward evening the patient had a severe chill followed by high temperature. On admission to Duvoir's service the next day, in addition to the marked febrile reaction there were all the symptoms and signs of a cardiovascular collapse. She died on the following day (forty-eight hours after being given the anatoxin injection). The necropsy revealed only a gross hemorrhage in the right and a microscopic hemorrhage in the left adrenal gland. It appears as though an extreme degree of intolerance toward the staphylococcus anatoxin existed in this patient.

In the discussion of Duvoir's case, Debre did not believe that death was due to a fault in the technique of preparation of the anatoxin, the result of which would be that the patient had received a large dose of staphylococcus toxin, because none of the other patients who had received the anatoxin on the same day as the patient had noted any ill effects. The case teaches that one should always test the sensitivity of the patient by injecting 0.1 cc of the anatoxin and observe the reaction following such a preliminary injection.

At the same meeting, two papers were read by Tzanck and his co-workers, one on the results, accidents and dosage of the anatoxin in skin and other staphylococcal infections and the other on a comparison between the antitoxin content of the blood serum and the therapeutic results. Of sixty-two patients with various infections of the skin and other superficial structures treated with the anatoxin, eighteen were markedly improved, thirty-five improved, three not improved and six are still being treated or have not returned. The most gratifying results were obtained in furunculosis and dermatitis of pyogenic origin. Axillary adenitis was resistant, in sycoes the result was good in one, but in three others the treatment was a failure. Reactions were infrequent and, when observed, only slight.

It is advisable before beginning the treatment to try an intradermal injection and note whether there is any reaction.

In his second paper, Tzanck stated that there was no relation between the antitoxin content of the blood serum and the action of the anatoxin. The serum may contain a high percentage of antitoxin and yet recurrence take place. On the other hand, a cure may follow the first injection and yet the blood serum contain very little antitoxin.

At the January 27 meeting of the Academy of Surgery, Sauve reported twenty-five cases treated with the Ramon anatoxin. As a prophylactic immunization measure, i. e., vaccination 0.5, 1 and 1.5 cc were injected at eight day intervals. In this group there were six successful results in cases presenting the sequelae of a septicemia. In the second group, in which anatoxin was employed as a therapeutic agent, there was one brilliant result in two cases of severe sepsis and one death. In four cases of carbuncle there was marked improvement in all.

In the remaining nineteen cases the results were not satisfactory. Sauve is of the opinion that the anatoxin is of greater value as a prophylactic than as a curative measure.

At the same meeting, Soupault and Bernardini reported a case in which they attributed the favorable outcome of a severe staphylococcal sepsis to the use of the anatoxin but which would appear to be the result of removal of the focus of infection (osteomyelitis of the ankle bone) by amputation of the leg. In a man, aged 48, there was a sudden lighting up of an old bone focus followed by symptoms of septicemia. Blood culture revealed the presence of *Staphylococcus aureus*. There was no amelioration following two injections of anatoxin at eight day intervals. After a third injection and an amputation on the twentieth day, the septicemia disappeared rapidly.

Capelle added two personal cases: one of staphylococcal osteomyelitis of the femur and the other an osteo-arthritis of the wrist with metastatic arthritis of the knee and the ankle. Both patients recovered rapidly following the use of the anatoxin.

### The "Silent" Periods of Diabetes

In the Dec 5, 1935, issue of *Marseille medical* Jouve-Balmelle directs attention to certain intervals in the course of diabetes in which all of the classic symptoms, even the glycosuria, either become very mild or disappear completely. A single examination of the urine does not suffice in order to recognize a diabetes or to determine the gravity of the individual case, because of the great variations in the degree of glycosuria. Of 192 typical cases followed over a long interval, forty six are of especial interest owing to the fact that despite diet and treatment, the glycosuria was constant. The same was true to a greater or lesser extent of the clinical symptoms.

In other of the 146 cases, both the clinical signs and the glycosuria disappeared completely at times during a period of observation of several years. Even though a more liberal diet was allowed, neither the clinical signs nor glycosuria recurred during these "silent" periods. Glycosuria is of variable duration, so that an exacerbation of the most severe type (acidosis, acute tuberculosis) may appear suddenly without apparent cause. The prognosis of a case of diabetes should not be based on the degree of sugar content of the blood or urine, because these vary from day to day. One cannot state that a case of diabetes is benign just because a single examination of the blood and urine show a slight elevation.

Even in the "silent" period the diet should be strictly adhered to.

### Convention of Nature Cure Physicians

In May 1935 the merger of various groups into a united "National Organization for a new German Medicine" (Reichsarbeitsgemeinschaft für eine neue deutsche Heilkunde) (*THE JOURNAL* Sept 7, 1935, p 811) took place. Among the groups which merged at that time were homeopathic and regular physicians, biochemists, nature cure physicians, kneippists, balneologists and psychotherapists. As the national fuhrer of medicine expressed it on that occasion this united organization has undertaken the task of bridging the gaps which separate the various systems and of synthesizing the tenets of the newer schools with those of the old. The Reichsarbeitsgemeinschaft held its first district group convention in Berlin (Jan 17 to 19) in conjunction with the third national convention of the Reichsverband der Naturärzte (National League of Nature Cure Physicians). This convention provided an interesting insight into the present state of the movement as well as many sidelights on it. The director of the nature cure group said at the opening of the meeting that now, since the representatives of all the many schools of biologic therapeutics have formed a

united organization, it is no longer a case of one medical group fighting another but of a united struggle to improve the nation's health. All forces are now combined in the campaign for a new German medicine. Our work must go on to completion, our goal must be the production of a healthier German race. The first report was given by Professor Dr Kotschau, director of the polyclinic of biologic medicine of the University of Jena and also director of the Reichsarbeitsgemeinschaft. His subject was "Methods and Aims of the Biologic Movement for the Foundation of a New German Medicine." Since an end of their theoretical separation had been publicly recognized, nature cure physicians and physicians of the old school must undertake together the unbiased examination of all therapeutic measures. The paracelsian method can no longer be regarded as fundamental, the infinitude of nature must not be bound to a narrow rational concept. The science of Paracelsus has tended to lead away from nature, the slogan of the present should be "Back to Nature." The prominence of biologic ideas in the weltanschauung of the new state has done much to influence and further nature science. The creation of a new school of German medicine presupposes a changed concept of the physician. With the new German medicine a new type of doctor comes into being.

Likewise interesting from many points of view were the remarks of Dr Finke, secretary of the National League of Nature Cure Physicians. He pointed out that for the past year several groups and societies of medical men (among others the Hydrotherapeutic Institute of the University of Berlin and the Nature Cure Method Clinic at Jena, the latter sternly opposed by the faculty of medicine) have been occupying themselves with questions of physical dietetics. "With the dawn of a new era, the guiding hand of government has pursued a course wholly in accord with the totalitarian philosophy of nature cure physicians." The world of the nature physicians corresponds precisely with that of the new political concept (staatsauffassung). Dr Finke then touched on various topics of general interest. The designation "practicing physician" (praktischer Arzt) must be avoided, he said because enough is implied by the term 'physician.' It is to be hoped that the legal provisions for the licensing of specialists will be repealed. This encouragement of specialization is opposed to the concept of the new German physician. The reason for this can be stated in a word: a nature cure physician treats all mankind, accordingly, he may think of himself as an ear, eye or skin specialist at one and the same time (*THE JOURNAL*, July 27, 1935 p 294). The nature cure physician handles surgical cases in his own way and in so doing may recognize no limit to his professional jurisdiction. At the same time he acknowledges the importance of surgery as a necessary technic within the framework of medicine. The world view attitude must be kept within bounds. This sketch of a so to speak responsible 'nature physician' tells the reader enough, further comment is unnecessary.

Dr Brauchle, director of the nature medicine clinic of Rudolph Hess Hospital in Dresden, compared nature medicine and mechanistic methods. The mechanist, he said is the man who disregards nature, who considers the removal of a tumor, for example as sufficient whose philosophy is "as many methods as there are diseases." The opposite biologic concept draws on all cosmic elements that nature has placed at the disposal of man. It repudiates the artificial synthetic method. Disease is the sum total of all defense mechanisms. Nature medicine accordingly, instead of fighting bacteria attempts to strengthen the defense mechanisms of the physical entity. One can speak with Paracelsus of a physician within man who strives for a maintenance of equilibrium. Whereas the old school of medicine masters only externalities, the nature physicians seek to liberate the inner forces of defense. Disease and pain may

both appear as results of a disturbed equilibrium, yet there may conceivably be a sharp distinction between them. Nature cure science may cure the disease but not the sufferings. Disease is a defense activity. Even if the organism were not diseased, it might perish from pain. Suffering is the sum of all weaknesses. Nature medicine requires, as Dr Brauchle emphasized, that together with treatment of disease must go instruction in a better conformity of life to nature. The hospitals must be expanded into educational centers for hygienic living.

"Coordination of Popular Medicine with the Medical Profession" was discussed by G Wegener, director of the national federation for hygienic ways of life in conformity with nature (Reichsarbeitsgemeinschaft der Verbände für naturgemasse Lebens- und Heilweise). He assailed mysticism and sectarianism. He spoke of the existing gulf between the medical profession and the public. This he believed should be bridged as soon as possible through the extension of nature cure methods, the medicine of future ages.

A series of reports gave an insight into various problems of the nature cure method, among others, its introduction into hospitals. The value of the kneippian nature cure method in diseases of childhood was stressed. The biochemists of today are harvesting the fruits of Kneipp's painstaking pioneer labors. Further papers dealt with nature cure science and dentistry, rheumatism of the soft parts and myogeloses, herb medicine, active articular rheumatism and the physician as an educator. The physician must instruct his patients in nature cure matters in order that they may in turn instruct others and live lives in harmony with nature, independent of the physician. Greater emphasis must be placed on the diet. What we eat and how we eat are equally important.

Dr Bastamer of Berlin presented an explanation of homeopathy which further demonstrated the willingness on the part of the various groups to synthesize their differences. The speaker, taking exception to some of Dr Brauchle's remarks, stated that in his opinion not every fever possesses a therapeutic effect and not every patient is able, *simul generis* to produce all antitoxins. Neither is it possible to treat every phenomenon of disease. Homeopathy understands the human being as a complex of psychophysical idiosyncrasies and assists the will to a self healing of the body. "Every remedy cures that which it produces." Thus Bastamer defined the homeopathic method. It was brought out in a discussion of medicinal plants that a study of phytogeography was an absolute necessity and that herb medicine would receive a greater impetus from it.

The paper read by Prof Dr J H Schultz of Berlin on "Methods and Aims in Psychiatry" was received with great enthusiasm. Dr Schultz posed the decisive question: To what degree does the psychic influence physical happenings? An approach to the solution of this problem must be by way of the hypnotic method. In hypnosis, changes are effected in organic functioning and the normal state is again restored. Numerous experiments lead to the conclusion that all functional occurrences can be changed by purely psychic influence. "Implications of psychic influence are as ample as life itself." Psychotherapeutic methods that lead to self healing often require long periods of time to elucidate the nature of a disorder the cause of which lies deep in the subconscious.

In the closing address of the meeting, Dr Kluth of Kassel contrasted the nature cure method with a menaced specialty of the old school, surgery. The knife will always be indispensable to medicine, but surgery too can profit from nature cure science. Psychotherapeutic measures are valuable before an operation. In postoperative treatment the nature cure method may be of importance when the detoxication of the body must be aided by fanning the breath and the transpiration. Thromboses and emboli may thus be avoided. On this subject each

patient must be made to understand that health comes from healthy heredity and from living in conformity with nature.

It is a significant fact that Dr Wagner, the reichsarbeitsführer, has accepted all the claims of the new movement. In order that all physicians may become better acquainted with therapeutic methods of nature cure medicine, an increase in the number of available sick wards wherein these methods may be practiced is indicated. As a sign of cooperative effort it is to be noted that the 1936 convention of the German Society for Internal Medicine will be held at Wiesbaden in conjunction with the convention of the reichsarbeitsgemeinschaft für neue German medicine.

In the proceedings, several professors of the Berlin Medical Faculty also participated, among them the surgeon Professor Magnus and the gynecologist Professor Wagner.

### Preservation of Menstruation After Hysterectomy

At a recent meeting of the Vienna Physicians' Society, Professors Kraul and O Frankl presented five female patients in whom it had been possible by plastic implantation of uterine mucosa to maintain the menses following supravaginal hysterectomies performed on account of myomas. The oldest case dates back four and one-half years. Heretofore this operation, like total extirpation, was always followed by permanent amenorrhea. All discussion of the physiologic need for uterine bleeding aside, it is a known fact that the menses have a great psychologic importance. Although the majority of women without a uterus feel well most of the time so long as the ovaries are functioning normally, others exhibit, together with postoperative amenorrhea, serious psychic disturbance and an inferiority complex. The idea that a monthly discharge constitutes a *sine qua non* of genuine health is with the latter deeply rooted despite assurances that on the ovaries rather than the uterus depends the presence or lack of complete femininity. It is likewise true that myomas are often successfully enucleated and the uterus left intact or, by extremely high supravaginal amputation, the menstruating uterine mucosa is preserved. As Frankl was able to demonstrate, the objective may be attained with the use of only a small implant. Many surgeons have endeavored in postoperative amenorrhea to implant endometrium in the fundus of the vagina or in the cervical stump. However, these implants in most cases soon underwent resorption. Now excellent results have been obtained by a new method. This consists of the implantation, after supravaginal amputation at the normal height, of a pedunculated flap of uterine mucosa (if possible from the posterior wall) in the freshened cervical canal. This flap usually heals over satisfactorily. From four to five weeks later the patient experiences a feeble beginning of menstruation which later becomes about normal. This modification of the customary myomectomy is not indicated in all cases. It does not increase the danger of the operation, however, and gives rise to no intrinsic complications. Should an attempt at plastic implantation of endometrium tissue fail, the patient has certainly suffered no injury; if it succeeds, the effect on morale is considerable. There are two methods that interference in cases of (bleeding) myomas may follow: the radical method of total extirpation, and the conservative method based on preservation of the uterus at any cost. Higher morbidity and mortality must be expected when the latter method is employed. Conservative surgeons are perhaps justified in the opinion that menstruation in addition to its other functions acts as a drainage valve for the supposed "menotoxins" and for premenstrual hyperemia of the pelvic organs. At all events, the Kraul-Frankl transplantation may

cause even the conservatives to decide more readily on a method of myomectomy which, although more radical, shows more consideration for the patient. In the discussion following the demonstration, the gynecologist Professor Adler said he welcomed the new procedure. Opinion was almost entirely favorable to a method of transplantation presenting such slight technical difficulties and of such psychologic benefit to the patient.

#### The Sense of Direction in Drivers

Official investigations of traffic accidents have repeatedly shown that drivers may hear the warning signal of a second vehicle well enough and yet turn out in the wrong direction and later maintain that the signal came from the opposite side. In most of the countries where drivers are submitted to rigorous examinations it is required not only that the candidates be able to hear well but that they be able to distinguish the direction from which a given signal comes. Preliminary tests showed to every one's amazement that only 50 per cent of the candidates having normal hearing were able on a crowded square to state from which direction a signal came. The question then arose: Is deficient "direction hearing" in human beings due to a loss of mobility of the auditory membrane over a span of thousands of years or can the deficiency be explained in terms of time differentiation and sound differentiation between hearing in the right and left ears? Subsequent tests demonstrated that the fault lay not in the sensory organ but in the local urban conditions. A sound coming from behind and reflected by a house on the right will pierce the right ear more forcefully, so that the driver believes the sound to come from that direction. When the tests were made on a wide treeless flying field, the number of errors was reduced to 7 per cent. On a completely reflex-free plain the number sank to zero. The reason why so many persons of normal hearing made such a poor showing in the examinations is simply and solely the reflection of sound in a big city. The city is to the ear, as it were, an acoustic maze of many sound-reflex surfaces. The examination of drivers in "direction hearing" is therefore without practical value.

#### High Mortality Among Viennese Physicians

The figures for recent years reveal that the death rate among physicians in Vienna is higher than the mortality rate of the entire population. During the last five years 13 per cent of the inhabitants died on the average each year (about 24,000 of 1,866,000). At the same time the number of old persons (over the age of 65) constantly increased. The membership of the Viennese medical profession increased during this quinquennium from 3,846 to 4,042. The mortality for the profession, however, amounted to more than 16 per cent and in recent months two or three eminent physicians passed away almost every week while in full bloom in their professional activities (between the ages of 55 and 65). No exhaustion of the supply has been perceptible, and the newer generation seems to be well enough represented numerically. Yet the formerly well established increase in the duration of life has come to a standstill, since the number of physicians over the age of 70 does not noticeably increase. Doctors engaged in academic activities that is, those who are members of the teaching staff of the medical school, seem to pass away more prematurely than the others. Three prominent physicians have died recently: one after the other, Docent Dr. Breuer, the internist and chief physician of the Rothschild Jewish Hospital, at the age of 67; Professor Dr. Karplus, aged 70, a neurologist; and Dr. Delme, head physician of the Vienna Municipal Children's Hospital, aged 55. All three men were distinguished teachers and representative research workers, all three were exhausted by the twofold duties of teacher and practitioner.

## Marriages

FRANCIS HENRY MCGOVERN to Miss Rebecca Cash Lee, both of Milwaukee, at Ivy Depot, Va., February 7.

RUTH J. FRANK, Spartanburg, S. C., to William Leonard Pugh, Ph.D., at Wooster, Ohio, Dec. 23, 1935.

STEPHEN MATTHEW LIANA Linden, N. J., to Miss Leona Bernice Budryk of Paterson, Nov. 28, 1935.

WILLIAM TURNER RAY, Charlotte, N. C., to Miss Harriett Mangum of Wake Forest, February 11.

DAVE B. RUSKIN, Fairgrove, Mich., to Miss Florence Rutenburg of Dayton, Ohio, January 26.

CLARENCE VEARN PARTRIDGE to Miss Edith Anne Pritchard, both of Mobile, Ala., January 21.

EDWIN P. PRESTON, Miami Beach, Fla., to Miss Josephine Montanus of Coral Gables recently.

## Deaths

Albert Moore Barrett, professor of psychiatry, University of Michigan Medical School, Ann Arbor, and director of the State Psychopathic Hospital, Ann Arbor, died, April 2, of coronary occlusion, aged 64. Dr. Barrett was born in Austin, Ill., July 15, 1871. He was educated at the State University of Iowa, Iowa City, where he received his A.B. degree in 1893 and his M.D. in 1895, and studied at the University of Heidelberg, Germany, from 1901 to 1902. In 1895 he became pathologist at the Independence (Iowa) State Hospital for Insane and served in that capacity until 1901. He was assistant physician to the Worcester (Mass.) Insane Hospital from 1897 to 1898 and pathologist to the Danvers (Mass.) State Hospital from 1901 to 1905. He was assistant in neuropathology at Harvard during 1905 and 1906. In 1906 he was called to the University of Michigan to organize the first university hospital and clinic in America for mental diseases. In the same year he was appointed associate professor of neuropathology at the university and medical director of the psychopathic hospital. He was professor of psychiatry and nervous diseases at Michigan from 1907 to 1920 and since 1920 had been professor of psychiatry. He was a past president of the American Psychiatric Association and the American Psychopathological Association and a member of the American Neurological Association, Association for Research in Nervous and Mental Disease and the Central Neuropsychiatric Association. Dr. Barrett was also a member of the Medical Council of the U. S. Veterans Bureau.

Ernst August Sommer, Portland, Ore., Willamette University Medical Department, Salem, 1890, in 1929 elected vice president of the American Medical Association, member and past president of the Oregon State Medical Society and the Pacific Coast Surgical Association, member of the North Pacific Surgical Association, a founder, a governor and past regent of the American College of Surgeons, emeritus professor of surgery, University of Oregon Medical School, formerly mayor of Oregon City, at one time member of the school board of Portland, served during the World War, chief surgeon to the Pacific Northwest Public Service Company, aged 66, on the staff of St. Vincent's Hospital, where he died, March 15.

Frank Stuart Mathews, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893, clinical professor of surgery at his alma mater, member of the American Surgical Association, fellow of the American College of Surgeons at various times on the staffs of the Home for Incurables, Hospital for the Ruptured and Crippled, St. Luke's Hospital and St. Mary's Free Hospital for Children, New York, Lawrence Hospital, Bronxville and the Mountainside Hospital, Montclair, N. J., aged 66, died, February 17, of heart disease.

Nathan Edmondson Berry Iglehart, Baltimore, University of Maryland School of Medicine, Baltimore, 1889, assistant in surgery, Johns Hopkins University School of Medicine, 1901-1909 and instructor, 1909-1918, on the staffs of the Johns Hopkins Hospital, Church Home and Infirmary, Woman's Hospital of Maryland, Union Memorial Hospital and the Bon Secours Hospital, aged 68, died February 1, of coronary thrombosis.

Benjamin Franklin Largent, McKinney, Texas, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, member of the State Medical Association of Texas, past president and secretary of the Collin

County Medical Society, fellow of the American College of Surgeons, served during the World War, surgeon to the McKinney City Hospital, aged 49, died, January 17, in a hospital at Dallas, of cerebral hemorrhage

**Horace Packard**, Boston, Boston University School of Medicine, 1880, member of the Massachusetts Medical Society, professor emeritus of surgery at his alma mater, a founder, formerly vice president and fellow of the American College of Surgeons, consulting surgeon to the Massachusetts Memorial Hospitals, member of the national committee of medical defense during the World War, aged 80, died, January 24, in Stoughton, Mass

**Hugo Otto Pantzer**, Indianapolis, Medical College of Indiana, Indianapolis, 1881, past president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, fellow of the American College of Surgeons, formerly clinical professor of gynecology, Indiana University School of Medicine, aged 77, died, February 14, in St Vincent's Hospital, of complications following a hip injury suffered in a fall

**Charles L Minor** ♂ Springfield, Ohio, Miami Medical College, Cincinnati, 1897, member of the American Academy of Ophthalmology, fellow of the American College of Surgeons, on the staffs of the Rickly Memorial Hospital and the Springfield City Hospital, aged 60, died suddenly, February 18

**George Alexander McCracken**, Woodville, Pa, Western Pennsylvania Medical College, Pittsburgh, 1905, member of the Medical Society of the State of Pennsylvania, medical superintendent of the Allegheny County Home and Hospital, aged 61, died, January 24, of carcinoma of the parotid gland

**Frederick Charles Kress** ♂ Johnstown, Pa, Jefferson Medical College of Philadelphia, 1897, fellow of the American College of Surgeons, formerly president of the board of health of Lilly, aged 63, on the staff of the Mercy Hospital, where he died, January 25, of a ruptured appendix and peritonitis

**Gustaf Richard Egeland** ♂ Sturgeon Bay, Wis, Northwestern University Medical School, Chicago, 1903, fellow of the American College of Surgeons, owner and medical superintendent of a hospital bearing his name, aged 59, died, January 30, in San Marino, Calif, of angina pectoris

**Walter Eugene Rahte** ♂ New York, University of Pennsylvania Department of Medicine, Philadelphia, 1901, formerly on the staff of the West Side Hospital and Dispensary, aged 59, died, January 29, in Milwaukee, of coronary thrombosis and chronic myocarditis

**John Vincent Ward Jr**, Weehawken, N J, Columbia University College of Physicians and Surgeons, New York 1924, served during the World War, on the staff of St Mary's Hospital, Hoboken, aged 37, died, February 26, of carbon monoxide poisoning

**William Otey McCabe** ♂ Thornton, Va, Baltimore Medical College, 1892, University College of Medicine, Richmond Va, 1894, past president and secretary of the Bedford County Medical Society, aged 65, died, January 18, of coronary occlusion

**Henry Stephen Fletcher**, Chicago, Dearborn Medical College, Chicago, 1907, formerly on the staff of the Welles Park Hospital, aged 63, died, January 20, in the Augustana Hospital, of ascending urinary infection and prostatic hypertrophy

**Thomas Conner Gorman** ♂ Cedar Rapids, Iowa, Rush Medical College, Chicago 1897, on the visiting staff of the Mercy Hospital and on the staff of the St Luke's Methodist Hospital, aged 61, died, January 24, of cerebral hemorrhage

**Howard Kemp Eaman** ♂ Bradford, Pa, Maryland Medical College Baltimore, 1910, past president of the McKean County Medical Society, aged 50, on the staff of the Bradford Hospital, where he died suddenly, January 22, of heart disease

**Joseph Cabell Jett**, Spring Dale, W Va, University of the South Medical Department, Sewanee, Tenn 1904, member of the West Virginia State Medical Association, aged 56, died, January 19, in a hospital at Baltimore

**Harry Moore Felton**, Pittsburgh, University of Maryland School of Medicine, Baltimore, 1905, member of the Medical Society of the State of Pennsylvania, aged 53, died, January 23, of chronic myocarditis and coronary occlusion

**John Joseph Greer**, Knoxville, Tenn, Vanderbilt University School of Medicine Nashville 1917, member of the Tennessee State Medical Association, served during the World War, aged 43, died, January 12, of pneumonia

**Hugh E Cureton**, Conway, Ark, Arkansas Industrial University Medical Department, Little Rock, 1895, member of the Arkansas Medical Society, also a pharmacist, aged 68, died suddenly, February 14, of angina pectoris

**George I Inlow**, Manila, Ind, Kentucky School of Medicine, Louisville, 1897, member of the Indiana State Medical Association, for many years coroner of Shelby County, aged 61, died, January 22, of parkinsonism

**John William Hess**, Adell, Wis, Wisconsin College of Physicians and Surgeons, Milwaukee, 1910, on the staff of the Sheboygan Memorial Hospital, aged 54, died in Sheboygan, January 18, of coronary sclerosis

**Patrick P Boggan**, Forrest City, Ark, Louisville (Ky) Medical College, 1874, member of the Arkansas Medical Society, health officer of Forrest City, aged 83, died, February 3, of cerebral hemorrhage

**James Franklin Gullic**, Koshkonong, Mo, Memphis (Tenn) Hospital Medical College, 1903, member of the Missouri State Medical Association, aged 56, died, January 17, of carcinoma of the breast

**Oley Alphonso Britell** ♂ Whitefish, Mont, Rush Medical College, Chicago, 1903, served during the World War, aged 57, died, February 7, of pneumonia and coronary occlusion

**Grover Augustus Stem**, Baltimore, University of Maryland School of Medicine, Baltimore, 1912, aged 46, died, February 5, in the Maryland General Hospital, of pneumonia

**J Willard Parrish**, Shelbyville, Ind, Medical College of Indiana, Indianapolis, 1896, for many years county health officer, aged 76, died, January 25, of myocarditis

**Donald Wright Broadbent**, Philadelphia, Temple University School of Medicine, Philadelphia, 1925, aged 39, died suddenly, January 24, of coronary thrombosis

**Francis Vaughan Fowlkes** ♂ Richmond, Va, University of Maryland School of Medicine, Baltimore, 1887, aged 68, died, January 20, of cerebral hemorrhage

**George Peter Michel** ♂ Buffalo, University of Buffalo School of Medicine, 1912, aged 56, died, Dec 17, 1935, in Cleveland, of rheumatic heart disease

**James W Sams**, Crestwood, Ky, Hospital College of Medicine, Louisville, 1901, aged 58, died, January 13, in Peoria, Ill, of an accidental gunshot wound

**Robert Clement Moakley**, Lexington, Mass, College of Physicians and Surgeons, Boston, 1915, aged 58, died, January 30, of carcinoma of the pharynx

**Lester Parker Hall**, Dixon, Calif, Cooper Medical College, San Francisco, 1897, aged 60, died, January 26, of pneumonia and cerebral hemorrhage

**Joanna Gaston Leary**, Elizabeth, N J, New York Medical College and Hospital for Women, 1887, aged 84, died, January 25, of chronic myocarditis

**Ada A Fowler**, Marion, Ind, Hahnemann Medical College and Hospital, Chicago, 1889, aged 77, died, January 23, of carcinoma of the breast

**Marion Crawford Aker**, Ritzville, Wash, Indiana University School of Medicine, Indianapolis, 1934, aged 30, died, January 20, of pneumonia

**Henry Andrew Benz**, Northbrook, Ill, Rush Medical College, Chicago, 1888, aged 72, died, Dec 7, 1935, in Chicago, of prostatic hypertrophy

**William D Rogers**, Coalmont, Tenn, Atlanta Medical College 1894, aged 68, died, January 20, in a hospital at Chattanooga, of pneumonia

**David Dee Goldberg**, St Louis, St Louis College of Physicians and Surgeons, 1899, aged 63, died suddenly, January 23, of angina pectoris

**John Joseph Spottiswood**, Mill Valley, Calif, Cooper Medical College, San Francisco, 1894, aged 64, died, January 14, of portal cirrhosis

**William Homer Sitton** ♂ Osceola, Mo, Eclectic Medical University, Kansas City, 1903, aged 54, died, January 23, of acute nephritis

**Clarence M McConkey**, Otis, Kan, University Medical College of Kansas City, Mo, 1905, aged 63, died, January 3, of influenza

**Frank Ramey**, East Point, Ky, Louisville Medical College, 1892, aged 69, died, January 21, of cerebral hemorrhage

**John William Fox**, Edinburg, Pa, Maryland Medical College, Baltimore, 1911, aged 57, died, February 8, of pneumonia

**Omer M Willis**, Metropolis, Ill, St Louis College of Physicians and Surgeons, 1898, aged 59, died, January 8

**L Otley Pindar**, Versailles, Ky, Medical College of Ohio Cincinnati, 1891, aged 65, died, January 2

**Mark O Pardee**, Franklin, Ohio, Cleveland Medical College 1895, aged 67, died, January 15

### PREGNANCY FOLLOWING SLOUGHING OF CESAREAN UTERINE SUTURES

To the Editor—In THE JOURNAL, May 7 1932 I described the passing, through the vagina, of the entire continuous interlocked catgut suture which had been placed on the outer surface of the uterus during the performance of a low cervical cesarean section, and stated that because of the good apposition of the thickened walls of the uterus it was likely that union would be good despite loss of the suture and ischemic tissues caught within. Since no rupture of the uterus during pregnancy had been reported following low cervical cesarean section, and since uteri have often been sutured tightly enough to cause ischemia of the tissues at the wound I have felt the prognosis for the next pregnancy to be favorable if section was performed without onset of actual labor.

A short time following this publication, Dr Irving F Stein of Chicago stated that the uterus was likely to rupture during a subsequent pregnancy or labor, also Dr D A Horner of Chicago reported a case in which the layers of continuous uterine sutures were passed in the lochia on the tenth day, followed by uneventful recovery.

Dec 19, 1935, four years and forty-eight days after the passage of the uterine sutures through the vagina, the patient was again delivered by low cervical cesarean section. Pregnancy had proceeded uneventfully except for a tenderness in the lower part of the abdomen and the back. During the last few weeks the patient became restless and complained of pain in the pelvis and distention of the external genitalia. At section a few adhesions were found but the old scar in the cervix could be located only with difficulty. The lower uterine segment was apparently normal. Tubal sterilization was done. Recovery was uneventful.

HARRY S FIST, M D, Los Angeles

### PURKINJE

To the Editor—A short while ago I was perusing THE JOURNAL of Nov 24, 1934 and on page 1583 came across the following excerpt from the Harveian oration by James Collier: "In 1835 Purkinje, an Austrian priest of Gipsy family." This is reprinted from the *British Medical Journal*. The original paper was published also in the *Lancet* Oct 20 1934. May I call attention to the enclosed reprint from the *Lancet* of Nov 3, 1934, which contains my exact statement of the facts with regard to Purkinje his family and his work.

To call J E Purkinje a gipsy evokes if I may put it that way an almost distressing feeling for Purkinje was one of the greatest men from our countries in fact one of the greatest physiologists or better to say scientists in the realm of medicine of the last century. J E Purkinje was born on Dec 17th 1787 in Libochovice in Bohemia—Bohemia is a country of Czechoslovakia in the same sense as Wales is a part of Great Britain—and was of Czech parentage. For a short yet excellent biography of Purkinje in English see the well known *History of Medicine* by Fielding H Garrison London Saunders 1917 p 475 et seq of the second edition which I have to hand.

It is really bad luck about J E Purkinje for the American Illustrated Medical Dictionary by Dorland the twelfth edition of which I have makes the incorrect statement that Purkinje was a Hungarian physiologist and that he died in 1850. In fact he was of Czech parentage and died in Prague in 1869. The editor of this dictionary promised on my request to correct it in the next edition.

Anthropological Institute, Masaryk University

Brno, Czechoslovakia

### "RECURRENCE OF INOCULATION MALARIA"

To the Editor—Dr M C Petersen in a recent article (THE JOURNAL, March 7 p 775) refers to the "recurrence of inoculation malaria." This emphasizes the importance of using a malarial strain in which no sexual forms of the parasite are found. In a series of articles published in the *American Journal of the Medical Sciences* 176 664 (Nov) 1928, 179 800 (June) 1930 and 184 262 (Aug) 1932, my associates and I have shown that approximately two and a half years is required to obtain a true biologic adaptation of the malarial parasite from a strain in which gametocytes occur to one in which they are absent. This has been done under the auspices of the New York State Psychiatric Institute and Hospital by continuous human passage of a sexual strain of malaria.

By using a strain of malaria in which no sexual forms are present the possibility of transmission of malaria by mosquitoes to other persons is precluded and furthermore the asexual forms of the malarial parasite yield much more readily to quinine than do the sexual forms.

NICHOLAS KOPELOFF, PH D, New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### THE IMMUNIZATION OF INFANTS AND CHILDREN

To the Editor—I have been immunizing a nurse aged 23 against scarlet fever with the Parke Davis toxin. There was no reaction following the first injection. A generalized rash and malaise followed the second injection. The third injection caused malaise, rash, headache, joint pains and a generalized edema most marked in the face. Would you advise continuation of the immunization? If so should the usual dose be given? In the case of an interval of two or more weeks between injections how should one proceed to complete the immunization? The patient states that she has an idiosyncrasy to epinephrine so this drug has not been administered with the toxin. Will you please advise a plan of immunization for infants and children against typhoid fever, scarlet fever, smallpox and diphtheria? Please give age when they should preferably be started and amount of the typhoid vaccine that should be used for infants and young children. Kindly omit name.

M D, Utah

ANSWER—The nurse is sensitive to proteins contained in the veal broth used for production of scarlet fever toxin. It is probably advisable to discontinue immunization in such persons if they have an idiosyncrasy to epinephrine.

The exact procedure in immunizing infants and children depends on the circumstances. If there is no known exposure to any of the diseases mentioned, smallpox vaccination is usually done first. Scarlet fever and diphtheria immunization may be given between 6 months and a year of age, and in case of exposure younger infants may be immunized. The reactions are less severe if the scarlet fever immunization precedes diphtheria immunization. The protection afforded by typhoid vaccine is not permanent and cases of typhoid in infants are uncommon. If the sanitary conditions in the community are good there is no need to vaccinate against typhoid until it appears in the community or the child is going to eat away from home.

### TREATMENT OF ANAL FISSURE BY INJECTION

To the Editor—I believe that anal fissures are being treated by injection as with quinine and urea but I am unable to get a description of the technic. Will you kindly describe this technic?

ROBERT HARTWELL M D Beaumont Calif

ANSWER—The treatment of anal fissure by injection was first described by Graham in 1923. In 1926 he reported the results in 128 cases and described his technic. He uses a small glass syringe to which he attaches a 27 gage needle and injects a 5 per cent solution of freshly prepared quinine and urea. The point of the needle is inserted about 5 mm away from the external margin of the fissure and the solution is injected beneath the base of the ulcer in such a manner as to raise it throughout its entire extent. About 1 cc of the solu-

tion is usually necessary. The patient experiences "rather severe pain" during the treatment, but on its completion local anesthesia has been produced. It is stated that during the following ten days or two weeks topical applications of silver nitrate and other medicaments can be made without causing pain and that the spasticity of the sphincter disappears. The treatment is usually completed in from two to three weeks.

This type of treatment has been advised in cases in which only the fissure is present. If external or internal hemorrhoids or other pathologic conditions requiring surgical treatment are found, it is better to include the fissure in the operation. Modifications of this type of treatment have been advocated. The object of these modifications has been to alter the solution in such a manner as to render the injection itself painless.

#### CARBON MONOXIDE HEADACHE IN GARAGE WORKERS

*To the Editor*—What can be done for frequent headaches that are common in garage workers as the result of the fumes of gasoline from the exhaust of automobiles? Acetylsalicylic acid gives no relief. Please advise treatment for these headaches both prophylactic and symptomatic or curative. Can you list references on byproducts of gasoline combustion which are the probable etiologic factors? Please omit name if published.

M D, Pennsylvania

**ANSWER**—The foremost source of headaches in garages is carbon monoxide. The average composition of automobile exhaust gas when the cars are operating on a level grade is

Carbon dioxide	8.6%
Oxygen	2.3%
Carbon monoxide	6.3%
Methane	0.9%
Hydrogen	3.0%
Nitrogen	78.6%

When motors are operating in garages, the percentage of carbon monoxide may be appreciably higher, particularly when the motors are first started, especially if the garage is unheated.

Evaporating motor fuels are second in order of importance as a source of headache. Gasoline represents a complex mixture of petroleum hydrocarbons but chiefly consists of pentane, hexane and heptane. Chief of these is hexane.

One gallon of gasoline burned in an automobile motor under specified conditions as to atmospheric temperatures and pressure produces 988 cubic feet of exhaust gas. It is computable that 622 cubic feet of carbon monoxide is thus produced. Even small cars discharge as much as 1 cubic foot of carbon monoxide per minute. As 0.01 per cent of carbon monoxide may produce headache, it is at once obvious that dangerous work conditions quickly may be brought about in garages. These statements chiefly are derived from the publication of the New York Academy of Medicine entitled "Carbon Monoxide Poisoning and the Automobile Exhaust" appearing in the Bulletin of the New York Academy of Medicine, August 1926 page 402. This publication, while old, remains one of the best presentations of the carbon monoxide hazard in garages and connected with the use of automobiles.

When headache is the sole manifestation of carbon monoxide poisoning, symptomatic and curative treatment is of relative unimportance. The obvious procedure is prevention. The concentration of carbon monoxide should be reduced below the threshold of any physiologic response. Motors long operated in the course of repairs should be hooked up with conduits discharging the exhaust gases into the general atmosphere. General exhaust systems should serve to prevent the accumulation of gases within garage areas resulting from the ordinary operation of motors. In most cities adequate testing devices are available, in public health departments or gas companies, suitable for the detection of even traces of carbon monoxide in the atmosphere.

#### TREATMENT OF SYPHILIS

*To the Editor*—I am treating a man aged 24, for syphilis. The Wassermann and Kahn reactions are four plus. His weight is 160 pounds (73 Kg). I have given him intravenously eight 0.6 Gm doses of neoarsphenamine and am now giving him intramuscularly two injections a week of a bismuth preparation. My plan is to alternate the arsenicals and bismuth preparation for one year with no rest period unless careful checkup necessitates change of plan. Would there be an unfavorable condition likely to arise should I substitute mapharsen for neoarsphenamine in the future treatment of the case?

M D Nebraska

**ANSWER**—The continuous system of treatment as planned for the patient for the ensuing year is particularly valuable in the treatment of syphilis in patients who are able to tolerate such intensive types of treatment. Care must be exerted to avoid the development of such treatment complications as dermatitis, hepatitis, neuritis and the blood dyscrasias. The results of the use of the continuous system as a rule are excellent if

the patient will follow the system and complications are not encountered.

As mapharsen is a recent development and clinical experience with it has been relatively short, it is too early to pass judgment as to its value. The inquirer has made no mention of how long the patient has had the syphilis, but the fact that he is 24 years of age would indicate that the disease was recently acquired. It would therefore seem advisable to continue to use drugs such as arsphenamine or neoarsphenamine, the value of which has been established by experience with it during the past quarter of a century.

#### EPIDEMIC STREPTOCOCCIC LARYNGITIS

*To the Editor*—For the past year I have been seeing cases the signs and clinical courses of which are suggestive of influenza of a mild type. Accompanying these crises is a markedly injected pharynx, involving the soft palate, uvula, tonsils and postpharyngeal wall. These areas are covered with fine red streaks. Occasionally there are slightly elevated punctate red spots. No ulcerations are present. At times the uvula and tonsils appear edematous. In most cases in which I have examined the nares the mucous membrane of the entire nose has the same appearance. Following the administration of salicylates or antipyretics the general symptoms subside in from twenty-four to forty-eight hours. There in a week or two the patients complain of general asthenia and lassitude and they develop a cough of a spasmodic nature, which occurs on arising in the morning and lying down in the evening. This cough is comparable to that which occurs in pertussis except for the whoop that accompanies it. Regardless of the various local applications such as mild silver proteins, silver nitrate and tincture or solution of mercuric iodine this injection of the entire throat persists for from four to six months. During this entire period the patient complains of a general feeling of not being well. Am I right in assuming that I am dealing with cases of influenza? Do you think that it is advisable to take cultures of these throats? Can you recommend some measures to hasten recovery or to eradicate the infections from the throats? Please omit name.

M D Pennsylvania

**ANSWER**—The description of the course of cases given is similar to that which has appeared in the literature previously, and the usual organism at fault is a hemolytic streptococcus. As there is no statement as to whether a laryngoscopic examination was made, the laryngeal and tracheal involvement can be surmised only by the presence of the obstinate cough that so closely resembles that of pertussis. Only a short time ago the laryngeal aspects of the condition referred to were described in an article by Herbert Tilley and Dan MacKenzie (Epidemic Streptococcic Laryngitis, *Brit M J* 2 3 [July 6] 1935). The course of these cases is protracted, as a rule the temperature at onset is not high and prostration is not great. The cough which is pertussis-like and violent may be accompanied by pain due to edema of the larynx. Occasionally, organisms other than the hemolytic streptococcus are present, such as *Micrococcus catarrhalis*. It would be advisable to take cultures of these throats. It might even be worth while to use a vaccine that is made from cultures in those instances in which convalescence is very slow. However, too much should not be expected from that method of treatment. Chronically inflamed tonsils should be removed and any sinusitis that is present should be cleared up, if possible. Apart from this, time is the greatest factor in the recovery.

#### SCARLET FEVER TOXIN BY MOUTH

*To the Editor*—In your issue of October 26 in reply to an inquiry as to the effect of swallowing scarlet fever toxin you say: "If the child was previously susceptible to scarlet fever and swallowed such an amount of toxin he has partially or completely immunized himself against the disease. It will do no harm. No treatment is indicated. If this is true why go to the trouble of five weekly injections with the possibility of severe reactions to produce immunity? Also if this is true why can't this toxin be used by mouth in treatment of the disease?"

EDWIN L. DRAPER, M.D., Champaign, Ill.

**ANSWER**—In an article entitled "Antitoxic Immunity Resulting from Administration of Toxin by Mouth" (*The Journal*, April 23, 1932, p. 1436) George F. and Gladys Henry Dick concluded that toxin administered by mouth may stimulate production of the corresponding antitoxin but that toxin administered by mouth is less efficient than considerably smaller amounts injected subcutaneously. Reactions sometimes occur following mouth administration as they do following hypodermic administration of the toxin. Such reactions in both methods of administration cause no permanent injury and do not require treatment. The principal objection to substituting the administration of toxin by mouth for hypodermic injection is that less than 3 cc of the undiluted toxin is required completely to immunize more than 90 per cent of susceptible persons by the hypodermic method, while approximately 500 cc of the undiluted toxin would be necessary to immunize about 70 per cent.

by mouth. It is improbable that mouth immunization will come into general use unless the volume of toxin can be reduced and the percentage immunized increased. At present the method is chiefly employed in such special cases as hemophilia or cardiac decompensation.

#### VAGUS PRESSURE IN TACHYCARDIA

*To the Editor*—Regarding the Query and Minor Note on paroxysmal tachycardia (THE JOURNAL July 27 p 302) I see no mention of deep hard vagus pressure in the neck when it comes to treatment. Also there is no mention of any treatment directed toward gastric or abdominal conditions. I happen to have had this disturbance ten or fifteen years ago at the age of 40. Dr. Hugo Freund and several other good men saw me including the heart man at the Battle Creek Sanitarium. Care in diet and smoking and drinking was all that was suggested. It was not until I was virtually carried into Dr. Harry Schmidt's office with a pulse rate of 200 or more that I was told of vagotomy and to press hard on the vagus nerves. This soon put an end to my trouble and although even now there are slight recurrences two or three times a year they can easily be checked by this procedure. Diet, smoke and drink have their effects in bringing on a gastric or abdominal distention—it seems more like a solar plexus blow—and this seems to me to be the dominant causative factor. This may all be old stuff to you but it was not to me or the many good men that I consulted. M D Michigan

*ANSWER*—The point is well taken. Vagus pressure, which is really stimulation of the carotid sinus, will stop the paroxysm of tachycardia in many more than half the cases. The carotid artery is palpated and pressed firmly by the palpating finger at the level of the bifurcation of the common carotid. Either side may be used, but usually pressure is more efficacious on the left. It is better not to press on the two sides simultaneously. If there is no result the position of the palpating finger may be changed up or down, along the course of the artery. It is frequently advisable to teach some member of the family how to stop the attacks by this means or the patient may be taught to do it himself. There are several other ways of stopping the attacks such as inducing nausea by tickling the pharynx, swallowing some large bolus or changing the posture in some particular way. Discussion of this will be found in Vaquez's textbook on the heart. It is interesting to note how many patients have found some way of stopping the attacks themselves. Gastric and abdominal conditions should always be considered, and frequently attention to diet and dietary habits will make the attacks less frequent.

#### PLASTIC SURGERY OF FACE

*To the Editor*—A girl aged 6 was struck in the face by a board five weeks ago. Inspection of her face at the present time shows a ridge which begins at the point midway between the corner of the eye and the nostril, runs just below the malar prominence and ends at a point about half way between the corner of the mouth and external auditory meatus. There is no tenderness or discoloration at present. On palpation with a finger inside the mouth the bony structures are found to be apparently normal while a ridge can be felt in the soft parts of the cheek. The impression from palpation is that of feeling the lower edge of a ruptured muscle which has retracted upward. Please inform me if this is a reasonable supposition and as to the prognosis. The present appearance is disfiguring. Please omit name. M D New Hampshire

*ANSWER*—If it was a bony displacement it is too late to correct it without radical cutting of the bone and if it is in the soft parts nothing is to be gained by any immediate attempted correction. It possibly might be due to a cutting of the muscle but more probably is an infiltration of the soft tissues resulting from overactive efforts at repair. Under any circumstances, nothing is to be lost by observing the case for several months and postponing any surgical correction until all possible natural repair has been accomplished.

#### FEVER TREATMENT IN SYPHILIS OF THE NERVOUS SYSTEM

*To the Editor*—I have a patient with syphilis of the nervous system the only evidence being the pupillary reflexes. Arsenicals and preparations of bismuth have been given and the blood and spinal fluid Wassermann reactions are negative. He has read of fever therapy and has asked me regarding the complete cure by such a method. What in your opinion is the answer to the query? While he is negative now under arsenicals I do not consider him cured.

GEORGE E. KNAPPENBERGER, M.D., Macomb, Ill.

*ANSWER*—This patient is not one that is suitable for fever treatment. The use of arsenicals and bismuth compounds is ample therapy for his mild clinical state and negative serologic reactions.

It is advised that this patient be given long periods of rest between courses of therapy.

Fever treatment is indicated only in dementia paralytica.

#### HEMANGIOMA OF ADNEXA

*To the Editor*—Please advise me what to do for an apparent hemangioma of the left adnexa revealed by laparotomy. The patient is a woman aged 27. No other pelvic disorder is present. Is radium or x-ray advised? Please omit name. M D Arizona

*ANSWER*—Hemangioma of the adnexa is unusual. If possible, an attempt should be made to remove it surgically. Subsequent treatment would then depend on the microscopic examination of the removed tissue. If it is malignant the pelvis should be thoroughly treated with high voltage x-rays administered from various portals. If benign, radiation therapy need not be instituted. Since the patient is so young, surgical attack may be considered in preference to irradiation so as to avoid an artificial menopause.

#### TREATMENT OF UTERINE FIBROIDS BY X-RAYS

*To the Editor*—In the treatment of uterine fibroids by x-rays does the tumor entirely disappear when the treatment is satisfactory?

FRANK E. WIEDEMANN, M.D., Terre Haute, Ind.

*ANSWER*—Fibroid tumors do not entirely disappear following satisfactory roentgen therapy; they undergo the same sort of involution which occurs at the menopause, that is, there is marked shrinkage in the muscular elements but the fibrous tissue persists. Of course if the fibroids are degenerated, calcified or cystic, little change in their size could be expected after radiation therapy.

#### FREEMARTIN AND INTERSEXUALITY

*To the Editor*—I was told by a stock breeder that in the case of cattle when twins are born, one male and one female, they usually do not reproduce. Does this hold true in man?

MILTON TRAUTMAN, M.D., Prairie du Sac, Wis.

*ANSWER*—In cattle, when twins of opposite sex are born, the female of the pair is usually an intersexual individual, called freemartin, and is sterile. The male of the pair is normal and fertile. In man, no comparable situation occurs in connection with twins, but intersexual individuals do occur, the origin of which is not well understood.

#### BELL'S PALSY

*To the Editor*—On page 727 of THE JOURNAL February 29 I notice two inquiries regarding the treatment of Bell's palsy. Of 337 cases referred to the Department of Physical Therapy at the Vanderbilt Clinic of the Columbia Presbyterian Medical Center only 142 cases existing more than two weeks failed to respond to treatment with diathermy and the static wave current. It was necessary to continue treatment for a period greater than twenty-four treatments using diathermy, galvanic motor point stimulation, massage and exercises before a mirror. Fifty-seven cases sent to the department that had existed less than two weeks responded to a few treatments of light and the static wave current. Ninety-two cases existing under two weeks did not clear up within a period of two weeks and were finally cleared up when galvanic motor point stimulation was added. The remaining cases considered old cases cleared up without any galvanic stimulation at all. Merely diathermy and the static wave current were applied. From an experience extending from 1928 to 1936 it is conclusively shown that heat in the form of radiant light or mild diathermy plus the decongestive effect of the static wave current is sufficient to bring about prompt relief of symptoms.

Cases of facial paralysis preceding or following mastoid operations do not respond to this treatment but can be successfully treated with the galvanic motor point. As the faradic current is irritating and cannot be measured in its intensity it has been entirely discarded in my clinic. These cases were all diagnosed by the outpatient department of the Neurological Institute where electrical reactions were tested but no matter if the long standing cases did show a reaction of degeneration galvanic motor point stimulation has been persisted in with most gratifying results. Lifting massage and exercises in front of a mirror twice a day at home by the patient are considered of great importance, but by far the most important factor in the treatment of Bell's palsy is the early institution of decongestive therapy.

NORMAN E. TITUS, M.D., New York

#### PERSISTENT SUPERFICIAL INFECTION

*To the Editor*—In THE JOURNAL February 22 in Queries and Minor Notes there is an inquiry under the heading Persistent Superficial Infection. While it is always hazardous to express an opinion and give advice in an entia I shall nonetheless endeavor to do this in the hope of really offering the patient in question and others similarly afflicted relief. The noncommittal answer to the inquiry further justifies this procedure. This is not the place for a detailed discussion of a diagnosis for that I would refer the inquirer to an article published by me in 1930 on recurrent lymphangitis (Minnesota Med. 13:902 [Dec.] 1930). The treatment consists of the injection of foreign protein intravenously and filtered roentgen therapy locally. My results by these methods have been eminently satisfactory.

WILLIAM H. GOCKERMAN, M.D., Los Angeles

## Book Notices

*The Treatment of Diabetes Mellitus* By Elliott P Joslin M D M A Medical Director George F Baler Clinic New England Deaconess Hospital Boston With the cooperation of Howard F Root M D Priscilla White M D and Alexander Marble M D Fifth edition Cloth Price \$6 Pp 620 with 9 illustrations Philadelphia Lea & Febiger 1935

For nearly twenty years, Joslin's "Treatment of Diabetes" has been the authoritative work in English on this subject, and the present edition, written with the cooperation of his associates Drs Howard F Root, Priscilla White and Alexander Marble, is no exception.

Prior to the advent of insulin, the major problem in the treatment of diabetes was the control of glycosuria and its attendant symptoms. Complications such as carbuncles and tuberculosis were fatal, but degenerative arterial lesions incident to diabetes of long standing constituted a comparatively minor problem because few patients with severe diabetes survived long enough for such complications to develop. At present, with insulin, the control of glycosuria is possible with the use of any one of a number of widely different diets, nevertheless the incidence of arterial disease has greatly increased and its prevention has become almost the chief concern of the clinician. Furthermore, many complications that formerly were almost invariably fatal to persons with diabetes are now amenable to treatment and carry a mortality only slightly greater than they affect persons without diabetes.

As one would anticipate, these changes in the nature of the diabetic problem are reflected in Joslin's new edition. For example, entire chapters are devoted to complications occurring in the digestive, nervous and genito-urinary systems and in the organs of special sense, as well as to tuberculosis, cancer, syphilis and diseases of the blood and skin affecting diabetic patients. As in previous editions, the problems incident to juvenile diabetes, infections, surgery and pregnancy in diabetes are discussed in detail.

In dealing with the relative merits of the high-carbohydrate low-fat diet versus the low-carbohydrate high fat diet, Joslin is inclined to pursue and recommend a middle course. The diets that he used in 1935 contained on an average about 150 Gm of carbohydrate. His attitude toward the problem can best be expressed in his own words: "Insulin and the use of the principle of undernutrition make the high carbohydrate low-fat diet possible, and now it is simply a question of time to determine whether patients with equally severe diabetes living upon diets containing more than 200 grams of carbohydrate will be better off at the end of ten or twenty years than those who have lived upon a somewhat lower value. The introduction of these diets has resulted in substantially raising the carbohydrate in the ration of the author's cases and of practically all diabetics throughout the world. However, we must wait for end-results." Unquestionably his judgment here is sound.

As in previous editions also Joslin objects to diets high in fat on the ground that a disturbed lipid metabolism is responsible for the high incidence of arteriosclerosis among patients with diabetes. For example, in the chapter on cardiovascular diseases revised by Root, this statement occurs: "I believe the chief cause of premature development of arteriosclerosis in diabetes, save for advancing age, is due to an excess of fat in the body (obesity), in the diet, and in the blood. With an excess of fat diabetes begins and from an excess of fat diabetics die formerly of coma, recently of arteriosclerosis." Further on in the same section he says: "Can it be that the prevalence of arteriosclerosis in diabetes is to be attributed to the high fat and high-cholesterol diets we have prescribed? This may be the case. At any rate it is reasonable to maintain the cholesterol in the blood of our patients at a normal level, and that I shall strive to do." It is apparent that Joslin was, and still is, impressed by Aschoff's modification of Virchow's imbibition theory of arteriosclerosis, which attributes arteriosclerosis to

physiologic strain and the imbibition by the arterial walls of plasma containing excessive amounts of lipids, especially cholesterol

To many students of metabolism this theory of arteriosclerosis has never been very satisfying and recently it has been subjected to critical scrutiny by C Lyman Duff (*Experimental Cholesterol Arteriosclerosis and Its Relationship to Human Arteriosclerosis*, *Arch Path* 20 81 [July], 259 [Aug.] 1935) Certainly the question is still open. The book would have been improved as a work of reference if some of the evidence against the lipid theory of arteriosclerosis had been included. Regardless of how one feels about this theory, no one can object seriously to Joslin's application of it in his plan of treatment, in which efforts are made to control the level of blood cholesterol as well as blood sugar. However, as Joslin is free to admit, lowering of the blood cholesterol usually occurs when diabetes is well controlled regardless of the type of diet used. Also an authors index would have made the book more useful. Technically the new edition otherwise has been materially improved. Its size has been reduced by nearly 400 pages. This reduction has not been obtained at the price of thoroughness and is a distinct advantage for the man who takes his reading matter to bed with him. In sharp contrast to much of the current medical literature the delightful personality of the author is evident in his work. His style, as always, is refreshing and his attitude toward the problems of the diabetic patient is unequalled in its sympathetic understanding. His book merits a place in the library of every physician.

Association pour la documentation photographique et cinematographique dans les sciences. II<sup>e</sup> Congres Paris 4 11 Octobre 1934. Compte rendu publie par les soins du Dr C Clouet et de J Painleve. Paper Pp 93 with illustrations. Paris. Librairie Moline S A 1935

The second congress of the Association pour la documentation photographique et cinematographique dans les sciences was held in the halls of the Musee pedagogique Paris Oct 4, 1934. The use of photography and cinematography is becoming an increasingly valuable aid not only in the teaching of students but also as a method of disseminating knowledge among laymen. The second congress consisted of lectures on numerous scientific subjects, most of which were illustrated with motion picture films. Among the papers published in the association's official journal is an article on autophoric transplantations by Professor Przibram of the Biologic Institute of the Academy of Science, Vienna. He demonstrated with five films the art of transplantation. He first demonstrated the transplantation of insects' heads, using for example the coleopteras. The head of a hydrophilus was exchanged with the head of a dytiscus. Other films demonstrated transplantations made on Orthoptera, *Dipopus*, cold blooded vertebrates and rats.

In his paper on recent progress in infra red photography, Dr Andre Charriou discusses radiations and colors the spectral sensibility of photographic emulsions material necessary for infra-red photography photography in total darkness and the application of infra-red photography to medicine zoology, botany, archeology and astronomy. Of medical importance is the use of the infra-red technic in cases of eczema. It is possible to demonstrate the changes in the subcutaneous small blood vessels directly under and surrounding the affected area. Dr Charriou has also been successful in making infra-red photographs of eyes affected with cataracts. The pictures revealed certain details that are not visible to the naked eye.

Dr Fischgold presented a paper on some roentgenographic documents on cardiac physiology. He employed the chronophotographic method of Marey in recording the various heart dimensions.

Dr Weyl discussed the possibilities of realization of psychologic films.

Motion picture films were used to illustrate the paper by Drs Guichard and Pelissier on the head in breast and bottle feeding. He points out that the correct method for holding an infant during feeding prevents certain buccal maxillofacial deformity.

Dr Charles Clouet discussed filmograms which is a method of recording various stages of plastic operations by a series of still pictures.

Jean Painleve presented a long and detailed article on photomicrography. He particularly stressed the importance of micro-

cinematography (time lapse motion photomicrography), both in black and white and in natural colors. Mr Painleve stated that photomicrography in relief would be very desirable, although the prospects of such a technic being developed in the near future is very remote.

Fourteen illustrations are found in the entire journal.

Lehrbuch der Endokrinologie für Studierende und Ärzte. Von Dr Tage Kemp und Dr Harald Ohkels. Nach dem Manuskript der 2. Auflage des Lærebog i Endokrinologi aus dem Dänischen übersetzt von Dr Lore Marx. Paper. Price 10 80 marks. Pp 224 with 92 illustrations. Leipzig. Johann Ambrosius Barth 1936.

This is a German translation by Dr Lore Marx from the manuscript of the second Danish edition of the 'Lærebog i Endokrinologi'. It is intended to be a brief summary of present knowledge of endocrinology as related to clinical medicine. Emphasis is placed on the morphology of the glands both normal and pathologic, clinical disorders are illustrated with photographs. The illustrations are unfortunately not uniformly well done, although the majority are useful. As with so many other attempts at preparing a brief summary of this complicated and fast moving field the text is seriously deficient in many particulars. Fundamental contributions by well known investigators are frequently omitted altogether or given but passing mention, among these are important works of Stewart and Rogoff on the adrenals of Hanson on the parathyroids, of Turner on the pituitary and mammary glands. Conversely, undue credence is given such ill founded theses as, for example, those of the sexual rejuvenationists. One amusing instance of curious terminology, probably deriving from retranslation of English to Danish to German, is that the 'emergency theory' of adrenal function is here designated 'Katastrophentheorie' (which at that, is perhaps not an inaccurate name for it). Provided its many deficiencies are kept clearly in mind, parts of this book may be useful for reference.

Über Gewebsoxydation bei B<sub>1</sub> Avitaminose und Inanition. Inaugural dissertation von Håkan Rydin [Aus Upsala Läkareförenings Föreläsningar N F Bd XLII heft 12]. Paper. Pp 183 with 26 illustrations. Upsala. Almqvist & Wiksells Boktryckeri A B 1935.

The question whether tissue oxidation is decreased as a specific effect of vitamin B<sub>1</sub> deficiency has engaged the attention of numerous investigators, and the published results have occasioned considerable debate. The fact that during any prolonged lack of vitamin B<sub>1</sub> there is failure to eat a sufficient amount of food and therefore inanition of varying degree has made it necessary to determine at the same time the tissue oxidation in inanition control animals. This inaugural dissertation is a detailed report of an extended investigation of this general problem. Pigeons were used as the experimental animals. Both the Warburg microspirometer technic and the Thunberg methylene blue method were used to estimate the degree of oxidation characteristic of muscle liver kidney, brain and blood cells taken from normal birds pigeons that had subsisted on a polished rice diet, and birds exhibiting varying degrees of inanition but not lacking vitamin B<sub>1</sub>. The effect of supplying crystalline vitamin B<sub>1</sub> also was investigated. Some idea of the scope of this research can be gained from consideration of the fact that, in addition to using two quite different technics for measuring the degree of tissue oxidation prevailing observations were made not only on groups of 'normal' and 'inanition control' birds but even on the same pigeon by means of an extirpation technic by which samples of an organ were taken during a preliminary period of subsistence on an adequate diet, then during a period of vitamin deficiency, and finally during a subsequent normal period. The fact that the results obtained by the two different methods for estimating tissue oxidation were not always the same, that listing of the organs for their oxidative capacities as revealed by these two technics did not give identical results, doubtless serves to explain many of the contradictions found in the literature. In general this work supports the view that the lowered tissue oxidation observed in vitamin B<sub>1</sub> deficiency is to be attributed to the accompanying inanition. With respect to the brain however, support was obtained for the view of Peters and his associates that vitamin B exerts a specific action on the oxidative processes occurring in this organ. The detailed data collected by this author are presented in thirty-one tables and important relationships set forth in twenty-six charts. The data are sufficiently detailed to satisfy the specialist in this field. This monograph should

constitute a valuable addition to the library of every student of the physiologic function of vitamin B<sub>1</sub>. The citations from the literature are sufficiently extensive to form a valuable list of references bearing on this subject

**Human Personality and the Environment** By Charles Macfie Campbell Professor of Psychiatry, Harvard Medical School Cloth Price \$3 Pp 252 with 11 Illustrations New York Macmillan Company 1934

"This book presents the substance of six lectures delivered before a lay audience," the author states in a preface. As he also recognizes, it is a somewhat heterogeneous mixture of scientific views concerning the structure of the body, the mechanisms through which its functions are integrated and the principles of genetics with unsystematic references to qualities of personality and tendencies to reaction culled from many different sources, medical, biographic and literary. The text is well written and full of interesting suggestions and illustrations, which even if they do not present a systematic philosophy do lead to an appreciation of the complexity and significance of the problem of personality and to the manifold lines of endeavor that must be followed for its elucidation. The book can be recommended without hesitation for reading by physicians generally

**The British Pharmaceutical Codex 1934** An Imperial Dispensary for the Use of Medical Practitioners and Pharmacists. Published by Direction of the Council of the Pharmaceutical Society of Great Britain Fabrikoid Pp 1768 London Pharmaceutical Press 1934

This volume is a companion to the British Pharmacopoeia 1932, a review of which appeared in these columns some time ago. In the book under retrospect one finds an authoritative survey of standards, including tests for identity, purity, methods of assay, pharmacologic action and therapeutic uses not only of substances in materia medica appearing in the British Pharmacopoeia but also of those found to be of value by experienced workers in the British dominions. The text is divided into four parts. The first part contains monographs on chemicals and on crude drugs of animal and vegetable origin, and in addition to the general description includes paragraphs describing the action and uses and a concise summary of the preparations, also indicating the manner in which the substance is most conveniently prescribed. The second part contains descriptions of surgical dressings including their requirements and method of quantitative estimation when essential, while the third deals with the formulary section, deflecting modern pharmaceutical thought. The fourth part comprises the appendices, containing considerable material, including various tables, lists of atomic and molecular weights, reagents commonly used in chemical and clinical testing, important drugs classified according to their use for specific effect in certain diseases, and substances bearing proprietary trade names, followed by a comprehensive index. There are peculiarities, which do not detract from the book. The volume is a contribution worthy of consideration in any scientific library and is of value to these interested as well as to pharmacists and medical practitioners, for whom it was primarily intended, particularly those of the British Empire

**Données anatomiques en vue de la chirurgie réparatrice mammaire** Par C. Clouet et I. Berthod Paper Pp 58 with 36 Illustrations Paris Librairie Maloine S A 1935

The authors feel strongly that in order to repair hypertrophied and other deformed female breasts correctly the surgeon should have a clear knowledge of the anatomic disposition of the structures concerned. The first part of this profusely but poorly illustrated monograph is therefore devoted to the anatomy of the breast and contiguous structures. The authors show that the mammary gland is anatomically associated with the cutaneous and subcutaneous systems and not with the pectoral muscles. Following the morphologic exposition, the authors deal with the various types of mammary ptoses and the mechanism of their production. They stress that the important factor causing pendulous breasts is distention of the suspensory apparatus of the breast due to elongation of the fascia superficialis. Any plastic operation for correction of a deformed breast rationally conceived ought to fulfil certain conditions, which include reconstruction of the suspensory ligament, which is in many cases a most difficult task to accomplish, preservation of the nutrition of the areola and nipple, preservation of the

innervation and of some of the galactiferous canals, and a scar as small as possible close to the areola. The authors describe their own operative method of complying with these desiderata. While not offering anything particularly new or original, the monograph is worth study by surgeons interested in plastic procedures on the female breast

**Complete Handbook on State Medicine** J. Weston Welch Chief Compiler Paper Price \$2.50 extra copies to same school 75 cents each Pp 158 Portland Me. Debaters Information Bureau 1935

This compilation is designed for the use of debaters of the question of state medicine. It contains a study outline of the subject with a bibliography, briefs for both sides, with rebuttals, and some general instructions on debating. There is a fairer distribution of the quantity of material between the two sides than in other handbooks prepared for the same purpose. Yet the statements of the Committee on the Costs of Medical Care are said to be "far ahead, in authoritativeness, of any other evidence that you can possibly quote in this debate," and no reference is made to the fact that the accuracy of these statements has been seriously questioned. The College of Surgeons is also quoted as endorsing sickness insurance, which the negative is encouraged to offer as an alternative to state medicine. There is no quotation of the resolutions against sickness insurance by the House of Delegates of the American Medical Association. It can only be said that the affirmative bias is less evident and the information on both sides more complete than in the majority of similar handbooks

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts Determination of Reputability of Medical School**—Dr. Henry Blank was graduated from the Chicago Medical School and obtained a license to practice medicine in Illinois. Later he applied to the Wisconsin board of medical examiners for a license under section 147.17 Wisconsin Statutes, which provides that the board "may license without examination a person holding a license to practice medicine and surgery

in another state, if in such state the requirements imposed are equivalent to those of this state, upon presentation of the license and a diploma from a reputable professional college." The board refused to issue the license, on the ground that it did not recognize the Chicago Medical School as a reputable medical college. Dr. Blank then instituted mandamus proceedings to compel the board to hold a hearing to determine the reputability of the school of graduation. The trial court entered an order in favor of the petitioner, Dr. Blank, and the board appealed to the Supreme Court of Wisconsin.

The petition for the writ of mandamus alleged among other things that, after several attempts by Dr. Blank to get the Wisconsin state board of medical examiners to grant a hearing to determine whether the Chicago Medical School was a reputable medical college, a meeting of the board was held, at which Dr. Blank appeared "but was not given his right to a legal hearing," that thereafter, because of protests of Dr. Blank, the board notified Dr. Blank's attorney that another hearing would be held and invited Dr. Blank to be present, that at this meeting three members of the faculty of the Chicago Medical School were present and were given a hearing, but that the board refused to permit Dr. Blank or his attorney to be present while representatives of the school were before the board, and that Dr. Blank's attorney then demanded of the board "a legal hearing for your [the] petitioner and that the testimony at such hearing be reduced to writing by a qualified stenographic reporter to allow transcription thereof for the purpose of a record of the proceedings and any necessary judicial review," and that the board refused this demand.

The general rule, said the Supreme Court of Wisconsin, governing the procedure of medical boards in determining the status of a medical school is as follows:

"The board may adjudicate the status of a medical college as to reputability either of its own motion or on petition of the college and where the law does not define the method by which the board shall pro-

ceed to determine the reputability of the college it may perform its duty in that regard in any reasonable way it may deem proper' 48 *Corpus Juris* 1093

'The board is not bound by the ordinary rules of procedure or evidence that apply in a court of law or equity' 21 *R C L* 367

The function of a court in controlling by mandamus the action of such a board was considered in *State ex rel Coffey v Chittenden*, 112 Wis 569, 88 N W 587. In that case a mandamus was sought to compel the state board of dental examiners to grant a license to practice dentistry and the court said

It is elementary that in mandamus proceedings to coerce any board in the exercise of quasi judicial power the sole legitimate purpose thereof is to set such board in motion to command it to act not *ho v* to act to exercise the judicial power vested in it not to control as to the conclusion to be reached

Since it [the law] requires the board to pass upon the reputability of the school in circumstances like those in this case and places no limit upon the methods by which it shall gather information bearing on the subject for decision it may proceed in any reasonable way and candidates for licenses must submit to its judgments unless they transgress the boundaries of reason and common sense

In the present case, the court said, the board gave reasonable notice to both the Chicago Medical School and to Dr. Blank, who demanded the hearing. Three members of the medical faculty of the school and Dr. Blank appeared before the board. There is no allegation that any evidence offered by them was rejected or that they were denied opportunity to present evidence. Dr. Blank's complaint was, not that he was not given notice, nor that he was denied opportunity to establish his claim, but that he and his attorney were not permitted by the board to be present when the members of the medical school presented their evidence, and that his demands for another hearing and to have a competent stenographic reporter take down and transcribe the testimony were denied. Dr. Blank, the court said, was not entitled to be present before the board when witnesses were being heard and his exclusion was not a denial of due process. Administrative boards, even though their functions are quasi judicial and involve the determination of questions of fact, are not bound to conduct their proceedings as courts ordinarily conduct theirs. Furthermore, a court may not compel an administrative board to have the testimony given before it taken down by a stenographer in the absence of a statute requiring this method of recordation of testimony. The board may take its testimony and keep its records in 'long hand' if it wants to.

Dr. Blank was not entitled, as a matter of right the court said, to have the board grant him any hearing. The present case is distinguishable from *State ex rel Milwaukee Medical College v Chittenden*, 127 Wis 468, 107 N W 500. In that case the Milwaukee Medical College was recognized by the state dental board as a reputable college. Another college preferred charges against it claiming that it was not reputable and the board, without giving notice to the Milwaukee Medical College, "resolved" that the college dental department was not a "reputable dental school." The Supreme Court of Wisconsin, in that case, held that the determination by the board was without notice to the college and the action was violative of the due process secured by the Fourteenth Amendment to the United States Constitution. In the present case the Chicago Medical School had never been recognized by the board as a reputable medical college. Nothing would have been taken away from the college and certainly nothing was taken away from Dr. Blank, the court said, by denying the request for a hearing. The board had theretofore determined that the college was not reputable, and the court pointed out it does not appear that its previous determination was not based upon facts sufficient to support it. If Dr. Blank was entitled to a hearing before the board for reconsideration of the matter so was every other graduate of the college that wanted a license in Wisconsin. If the facts are such that the school is reputable under the Wisconsin law or was so at the time Dr. Blank received his diploma from it, Dr. Blank's remedy the court said is not to mandamus the board to grant him a hearing but to mandamus it to grant him a license.

The action of the trial court in issuing the order against the board was therefore reversed, and the record remanded with instructions to deny the petition for the mandamus—*State ex rel Blank v Granlung (W's)*, 262 N W 614

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Incidence and Biologic Characteristics of Hemolytic *Bacillus Coli* in Chronic Ulcerative Colitis**—Nicholls made cultures of 135 proctoscopic smears from forty-two patients with chronic ulcerative colitis and found the hemolytic form of *Bacillus coli* in eighty-four, or 62.2 per cent, of the samples. In forty-five of the eighty-four cultures the hemolytic bacillus was present in large numbers (from 50 to 100 per cent). If only the first swab specimen is considered from each patient hemolytic *Bacillus coli* organisms were present in twenty-six, or 61.9 per cent, of the forty-two cases. Repeated swab cultures were obtained from twenty-eight of the patients, the number varying from two to ten from a single patient. Specimens were taken at intervals ranging from one week to several months and thirteen patients were studied over a period of from one to two years. In twenty-two or 78.6 per cent, of the twenty-eight patients hemolytic *Bacillus coli* was present in at least one of the specimens studied. In the six negative cases four patients had only two cultures and two had four cultures. In incidence and biologic characteristics, hemolytic and non-

hemolytic strains of *Bacillus coli* recovered from the proctoscopic smears of the patients differed in no respect from those obtained from stool specimens of healthy subjects.

**The Takata-Ara Test of Liver Function**—In order to test the value of the Takata-Ara reaction, Magath performed the test in a series of eighty-six consecutive cases. In each case also a bromsulphalein test was performed simultaneously. Qualitative and quantitative van den Bergh tests were done in eighty-three cases, and quantitative determinations of protein were made in sixty-two cases, all the tests being done on sixty-one patients. The patients were carefully studied clinically, with especial reference to the possibility of disease of the liver. The condition of the liver of twenty-seven patients was observed either at operation or at necropsy. The diagnosis of cirrhosis was made in twenty-five patients, of whom sixteen gave a positive Takata-Ara test, however sixteen other patients with out cirrhosis also gave positive tests. Hepatic disease of some kind was diagnosed in fifty-three patients, the Takata-Ara test being positive in twenty-eight and negative in twenty-five instances. With four patients who apparently did not have involvement of the liver the Takata-Ara test was positive. Of nine patients with malignant conditions involving the liver, seven gave a positive Takata-Ara reaction. The negative tests in cases of disease of the liver were for the most part obtained in cases of early lesions, or relatively small ones, and obstructive lesions did not usually result in positive tests. There was no evidence to suggest that changes in the total protein of the serum could be correlated with the Takata-Ara tests. In only about half of the cases in which there was reversal of the albumin-globulin ratio was the liver involved, and in nine out of twenty-one cases of cirrhosis the ratios were reversed. Only one case, that of a hypernephroma, gave a reversed ratio and one in which involvement of the liver was not diagnosed. It is possible that the fibrinogen content of the serum has an influence on the Takata-Ara reaction and may account for Takata's results in cases of pneumonia. The correlation between the Takata-Ara test and the bromsulphalein test was not high, only half the cases that showed dye retention gave a positive Takata-Ara test. Direct van den Bergh reactions were present when twenty-two Takata-Ara tests were positive and when twenty were negative. In nine cases with positive Takata-Ara tests the van den Bergh reaction was indirect. In four of these cases the liver was not involved. Of the ten patients in the series diagnosed as having syphilis, five had a positive Takata-Ara test, the liver was evidently involved in these five cases. The van den Bergh reaction was direct in thirty-nine of fifty-two cases in which the liver was involved and in two in which the liver was not involved according to clinical diagnosis (hypernephroma and hemolytic jaundice). In fifty-one cases in which the liver was involved by disease the dye test was positive. The test was positive also in three cases in which the liver was thought to be uninvolved (arthritis, hypernephroma and facial neuralgia). In these three cases the dye remained was just sufficient to report the test as grade 1 (6 per cent of dye retained). In two cases there was evidence to justify the clinical diagnosis of involvement of the liver, but the report of the dye test was negative. These two cases were of tertiary syphilis with clinical manifestations of hepatitis but with no positive laboratory tests, and of recurrent cholangitis, respectively, tests being done during a remission. Of sixteen cases in which dye retention of grade 1 was present, involvement of the liver was surely present in thirteen and probably was present in one other case.

**Control of Acidity in Peptic Ulcer by Aluminum Hydroxide Drip**—Woldman and Rowland believe that the nasal drip method of continuous twenty-four hour adsorption of gastric acidity by aluminum hydroxide has promise of definite usefulness in the treatment of the acute stage of peptic ulcer. If reliance is placed on antacid treatment, there is every reason to carry it out in the most thorough and continuous manner. The aluminum hydroxide drip is free from the danger of alkalosis and of secondary acid secretion. The method is entirely compatible with any type of dietetic or sedative treatment. Because of continuous neutralization the diet can be suited more definitely to the nutritional needs of the patient rather than crowded in frequent feedings to control acidity. Functional rest of both the secretory and motor function of the

stomach may be allowed in larger measure Especially for the intractable case, before surgery is resorted to, the method represents an additional refinement of technic in medical management About 200 cc of 7 per cent colloidal aluminum hydroxide is added to 600 cc of distilled water, which, allowed to drip into the stomach at the rate of 5 or 6 drops per minute, will require twenty-four hours for its consumption

**Poisoning Due to Ingestion of Mixture of Sodium Bicarbonate and Sodium Fluoride**—Geiger reports the fact that a mixture of sodium bicarbonate and sodium fluoride, sold in bulk as sodium bicarbonate, was responsible for poisoning in twenty one reported instances, three of which terminated in death Samples submitted by those made ill and by members of the families of the deceased and those obtained by the inspectors of the department of public health from the various sources involved (except those from intact barrels of the original product) consistently showed arsenic and fluorine on qualitative chemical analysis, on quantitative analysis these samples were found to contain varying proportions of sodium bicarbonate and sodium fluoride, demonstrating a heterogeneous, "spotty" or "pocket" distribution The epidemiologic picture, at first confused by the positive reactions indicating the presence of arsenic in the specimens of "baking soda" and of commercial sodium fluoride was clarified through further study, which brought out the fact that hydrofluoric acid found through the reaction of hydrochloric or sulfuric acid with the sodium fluoride of the mixture dissolved the glass of the containers and released arsenic from it in sufficient quantities to give positive reactions for arsenic Recheck tests in petriolatum lined glass containers gave consistently negative results for arsenic It should be emphasized that there is no danger from sodium bicarbonate of standard brands sold in good condition, in the original package The incident should awaken interest in the real and potential hazards existing in the salvage of foods and drugs and the need for effective legislation that will require and provide adequate official supervision and regulation over all persons, firms and corporations dealing in foods and drugs This incident should serve as a warning and give impetus to the medical profession federal authorities and officials to secure adequate control over the labeling manufacture, distribution sale and use of insecticides particularly those containing fluorine

**Histidine Treatment of Peptic Ulcer**—Since January 1935, Wilhelmy and Hashinger have treated and carefully followed twenty-six unselected cases of roentgenographically proved peptic ulcers The method of procedure has been the daily injection of 5 cc of 4 per cent histidine monohydrochloride for a period of twenty-four days No untoward complications or reactions have been encountered nor has any patient complained of soreness or discomfort from the treatment The average duration of symptoms for the entire series was 87 years A typical ulcer history with epigastric distress one or two hours after meals intermittence with food and alkali relief were present in about 85 per cent of the cases Roentgenographic observations were checked immediately after treatment and again from two to four months later with the following results Four were considered cured four improved and the remainder unimproved Those cases considered cured were the ones in which no remaining evidence of ulcer could be detected Decrease in the size of the ulcer and lessened gastric motility was the basis on which four cases were classified as roentgenographically improved Marked roentgen improvement with no clinical relief was shown in one case The clinical results of the series show seventeen cases or 65.4 per cent, with complete or partial relief, and nine cases or 34.6 per cent, with no clinical improvement Of the seventeen cases, thirteen were completely relieved and four were partially relieved Because of the natural tendencies of peptic ulcers to heal or become symptom free for varying periods of time without any treatment, no definite conclusions can be drawn until these cases, and many more, have been followed for a period of several years It is apparent, however, that here is a method of treatment that will at least give symptomatic relief in about the same percentage of cases as the authors' former method of procedure, which consisted of a modified Sippy regimen

**Hypothesis for Origin of Renal Calculus**—Randall believes that there are but two basic causal factors capable of initiating the development of a stone in a renal pelvis The difference between these two causal factors can be sharply delineated and the resultant stone should be termed a "primary" or a secondary renal calculus depending on which of these two causal factors is present In the first class or the primary renal calculus one finds those cases in which the clinical picture is especially clear To it belongs the individual in otherwise perfect health who is suddenly seized with the clinical state known as calculus colic It is the author's firm conviction that such a calculus has arisen as a gradual crystallization on a lesion in the renal pelvis Somewhere in the renal pelvis, most probably on a papilla or in the papillary-caliceal angle, there has occurred a primary ulcerative lesion It is small but with

a raw surface, and the precipitation and coalescence of urinary salts have occurred on it. The salts so precipitated are those which at that time are especially supersaturated in the urine. As such the deposit starts and, once started, has every reason to increase gradually in size. Being so fixed, it gives no symptoms of its presence until, owing to some factor, be it trauma, size, weight or sudden motion, it ceases to be a fixed concretion and breaks loose from its point of origin. The next natural course is nature's effort to extrude the calculus down the ureteral line of drainage, with the result that one sees the patient in acute ureteral stone colic. Primary papillary or caliculi ulceration is of much more frequent occurrence than supposed. Such ulceration may be infectious, trophic or allergic. The facts demonstrated by Lieberthal and von Huth in renal tuberculosis are pregnant with possibilities in regard to the more frequent occurrence of pelvic ulceration in other infectious states. In the second class belong the calculi formed in a renal pelvis in which urinary stasis is present because of some obstruction to the normal urine outflow. It has been the tendency to look at this picture in a reverse order, making the stone the cause of the hydronephrosis rather than the resultant effect or complication of a hydronephrotic pelvis. To the author this picture is closely akin to the recognized condition as seen in vesical calculus. As the first class which forms as crystallizations on pelvic ulceration, is termed "primary" renal calculi, so this second class, postulated on faulty pelvic drainage, is called "secondary" renal calculi. The actual origin of the secondary renal calculi demands nothing more for a nucleus than a cluster of desquamated cells, a bacterial clump or a tiny clot of blood. They are easily assimilated into the clinical pabulum as the familiar vesical stone, and on equally parallel lines runs the observed fact that, when all the essential factors appear to be present for a stone's growth, it does not of necessity materialize. There is no doubt that in these secondary stones, formed of varying chemical laminae, certain salts at certain epochs reach the threshold of their insolubility in such a supersaturated liquid as the urine and precipitate in pure form over a period of time. Under these conditions there will be periods when one type of salt will be more easily precipitated than others, and the laminations will correspond to exactly such periods. Likewise the growth of such stones varies according to the type of deposit then being made. The factor of supersaturation of a urinary salt becomes of greater consequence the more one dwells on these facts and as such lends greater weight to the role of colloidal chemistry.

Elliott Treatment of Pelvic Inflammatory Disease R Fallas Los Angeles—p 88

**Cesarean Section**—Arnot states that low cesarean section, routine vaginal cleaning before operation, fewer vaginal examinations in cases not progressing well in labor, improved technique and the frequent use of blood transfusions were the chief reasons for there being no maternal deaths in ten and one-half years (356 cases) in his hospital. There was no relationship between the incidence of morbidity and the number of hours the membranes had been ruptured, the patient not being in labor. Neither was there such a relationship in the group of patients who went into labor without ruptured membranes. But when the patient was in labor and the membranes had ruptured, time definitely increased the incidence of morbidity. The test of labor, with or without ruptured membranes, was the biggest causative factor in cases in which there was fever for ten days or more. Previous cesarean section gave a considerable immunity toward infection, while other types of previous laparotomies decreased it slightly. Previous vaginal delivery conferred little or no immunity.

\*Early Oxygen Injection of Joints to Prevent Adhesions New Procedure E B Henson Charleston—p 85

**Early Oxygen Injection of Joints to Prevent Adhesions**—Henson has had continued good results for six years with the use of oxygen or air injection of joints to break up adhesions. Experience has shown that some joint capsules can be made to expand more than others with the same known pressure, therefore, for inflation, not more than 1 or 2 pounds of pressure should be used. Oxygen has replaced air, because oxygen stimulates synovial secretion. A dry joint is no longer dry after oxygen injection. By frequent injections of acute infective joints, the danger of dense adhesions is greatly lessened and many stiff joints may be prevented. For insufflation as much fluid as possible is withdrawn from the joint and then as much oxygen as the patient will tolerate is injected. The patient should be given morphine prior to injection. In inflating chronic joints the pressure is tested so that on the first injection not more than 2 pounds is registered. This is done before the needle is inserted into the capsule of the joint. The needle is inserted into the knee joint just below the patella, an effort being made to get a space between the bones, and the pressure is then turned on and it is stopped as soon as the patient complains of pain. While the needle is still inserted the oxygen is cut off and a roentgenogram is made to get some idea of how much oxygen is actually within the capsule. The apparatus used is described.

**Anterolateral Thoracoplasty in Pulmonary Tuberculosis**—Thevarthundil points out that a technic of thoracoplasty, based on the power of retraction of the lung rather than on compression from without, is being perfected. The lung is traumatized not only during its movements but also in repose in a distended state. The regions of maximal movement of the hemithorax in the upper, middle and lower parts of the thorax are the anterior anterolateral and lateral parts respectively, the posterior surface moving comparatively little. The lines of maximal dynamic trauma coincide with the line of maximal static trauma. In anterolateral thoracoplasty, an attempt is made to give repose to the lung by the elimination of the dominants, i.e., to interrupt the chief lines of traction of the thoracic wall on the lungs. The operation consists of a phrenic exceresis combined with the removal of variable lengths of ribs along the line of maximal movement. While it is admitted that an anterolateral thoracoplasty will not produce much immediate lung collapse, the author claims that it brings about considerable immobility of the hemithorax and allows lung retraction and rest. The operation being less traumatizing and shock producing than a posterior paravertebral operation it can be used with benefit in cases less chronic than those usually selected for posterior thoracoplasty and in cases in which the general condition of the patient does not warrant a serious compression operation.

\*Phrenicectomies or Phrenic Alcoholizations W Julien —p 28

**Phrenicectomies or Phrenic Alcoholizations**—According to Julien, the promise originally offered by phrenicectomy has not been fulfilled. Its principal disadvantages are that it paralyzes the diaphragm without insuring favorable therapeutic results, it sacrifices healthy pulmonary tissues, and it may cause accidents. Alcoholization of the nerve has some of the same disadvantages, but its effects are only temporary. The author feels that alcoholization has the advantage of avoiding the mechanical trauma produced by phrenicectomy and of allowing a tentative trial of the effect instead of a final irreversible one. He feels, therefore, that alcoholization of the phrenic nerve is usually preferable to phrenicectomy in cases in which pneumothorax is inadvisable. Ambulatory treatment is of course wholly inadvisable.

Some Remarks on Bony Pegging of Diaphyseal Fractures H Lafitte —p 51

**Cryptoleukemias**—Emile-Weil and his co-workers define as cryptoleukemias the hyperplastic blood processes that are not characterized by the appearance of the abnormal cells in the blood stream. The white blood picture thus remains quantitatively and qualitatively normal. The routine diagnostic puncture of the spleen in all cases of splenomegaly throws considerable light on the blood diagnosis of this nature. Three forms of cryptoleukemia can be differentiated in this way. The most common are the lymphatic cryptoleukemias. Myeloid cryptoleukemias can also be identified. Finally leukoblastic or acute cryptoleukemias sometimes occur. The clinical recognition of these forms is now possible by means of splenic puncture. The nature of the splenomegaly, the prognosis of the disease and the speed of evolution are largely clarified. Dangers of mistaken therapeutics are also avoided and often lead to roentgenotherapy.

**Speed of Circulation and Treatment of Heart Disease**—Godel and Chehale report a practically simple method of measuring the speed of circulation and the value of these measurements in following the course of heart disease. The principle of the method consists in noting the time in seconds that elapses between the moment of injection of purified ether and sodium dehydrocholate in the arm vein and the time when the first substance is noticed in the pulmonary air and the second in the lingual mucosa as a bitter taste. The first time depends on the speed of circulation in the segment corresponding to the activity of the right ventricle, the second corresponds to the activity of the left cardiac cavities. The injection should be made under basal conditions and after fasting for at least six hours. The patient must be told what sensations to expect and to note the exact time when they occur. The time is noted with a stop-watch. The normal relation of the two phases was worked out on about 100 normal persons and was found to be about equal. Every change in the relationship is abnormal and must be considered to indicate a pathologic state. Usually cardiac insufficiency is reflected by a prolongation of the circulation time (lengthening of the time of the test). Sometimes this is due to one segment and sometimes the other or both may be affected. The test shows changes in equilibrium between the two segments and thus allows the course of functional changes due to therapeutic measures to be followed with greater accuracy.

 \*Intratracheal Injections of Water in Treatment of Tuberculous Hemoptysis G Pennetti—p 114

**Intratracheal Injections of Water in Treatment of Tuberculous Hemoptysis**—Pennetti in 1933 reported results which he obtained in the treatment of tuberculous hemoptysis by supraglottic intratracheal injections of distilled water. Hemoptysis was controlled after one or several injections in twenty patients out of a group of tuberculous patients in whom the hemorrhages were not controlled by the hemostatics commonly used. The author interpreted the results of the treatment as due to a reflex caused by the entrance of the fluid into the respiratory tract, in which phenomenon, however, the nature of the liquid injected does not interfere. The author at this time discusses two articles published after his and related to his work. D'Angelo tried Pennetti's method in twenty cases of tuberculous hemoptysis of different intensities and came to the following conclusions: 1. The hemostatic action of distilled water is immediate and permanent in mild forms of hemoptysis, less efficient in types of medium intensity and negative in grave forms which, however, are controlled by intratracheal injections of epinephrine. 2. The therapeutic effect of the injections is due to a reflex (Pennetti's) originated by the introduction of a liquid into the respiratory tract and to another reflex of local vasoconstriction due to the action of epinephrine. Pennetti verified his previous results in a new series of eighteen cases and concluded that (1) the more or less prompt hemostatic action of the injections of distilled water and the duration of hemostasis after the injections are not related to the intensity of hemoptysis and (2) generally in grave hemoptysis satisfactory hemostatic results are obtained, but when water injections fail, epinephrine injections fail also. The second article discussed by Pennetti is by Ponticaccia, who said 'Pennetti, Ciannella and D'Angelo have confirmed my statements and sometimes have succeeded in checking hemoptysis by intratracheal injections of distilled water.' Pennetti says that both statements are wrong. His work dates from 1925 to 1933 and neither before nor since did he know of any work of Ponticaccia related to this matter. It is possible, however, that Ponticaccia may have practiced the method without reporting it. As to the statement that sometimes hemoptysis is checked with water injections, the contrary is exactly what happened: that is, only in rare cases is hemoptysis not controlled by intratracheal injections. The author gives these explanations to defend the paternity and value of the method: the rapidity of which in controlling hemoptysis surpasses all previously known hemostatic methods.

 \*Pathogenesis and Treatment of Hyperthyroid Diarrhea A Richieri—p 310

**Hyperthyroid Diarrhea**—Richieri says that increase of the thyroid secretion in the intestine alterations of the pancreas or the intestinal absorption, vagotomy or existence of hypochlorhydria and anachlorhydria are the most common hypotheses given in the pathogenesis of hyperthyroid diarrhea. The most important pathogenic factor is vagotomy produced by direct stimulation of the vagus by the hyperfunctioning thyroids. The modifications of the glandular secretions, especially the gastric, have a secondary influence in the production of diarrhea. The symptomatic treatment consists in the administration of epinephrine (two or three daily enemas of 15 or 20 drops of epinephrine in 200 cc of water), atropine (0.0005 or 0.001 Gm daily) and belladonna (15 drops orally two or three times a day). Opiates may be used in emergencies

The two essential causal treatments are roentgen irradiations and surgery of the thyroids. The medical treatment is indicated in certain cases as coadjuvant to roentgen and surgical treatments. Iodine is indispensable. The principal indications of the iodine treatment are emergencies in hyperthyroidism and the preoperative care of the patient. The most favorable time for performance of the operation is when the figures of the basal metabolism are almost normal. Other satisfactory medical treatments are 3,5 di-iodo-4-oxyphenylalanine in a daily dose of from 0.01 to 0.03 Gm, quinine or quinidine from 0.6 to 1 Gm, the sedative drugs of the nervous system and ergotamine tartrate (gynergon). Antithyroid serum does not produce constant results. Exophthalmic and toxic goiters should be differentiated for therapeutic purposes. Roentgen irradiations give satisfactory results in latent and larval forms of hyperthyroidism and exophthalmic goiter and does not have the possible dangers of thyroidectomy. Richieri advises a combined medical and roentgen treatment in exophthalmic goiter and subtotal thyroidectomy (after preoperative care of the patient by rest administration of iodine and 3,5 di-iodo 4-oxyphenylalanine) in (1) exophthalmic goiter after the failure of medical and roentgen treatments, (2) exophthalmic goiter with compression and (3) toxic goiter.

 Aseptic Lymphocytic Meningitis After Suboccipital Puncture H Kuba—p 300

**Late Posttraumatic Epilepsy**—Meyer asserts that severe cranial traumas always remain a source of further complications, even if the direct results take a favorable course. This applies particularly to shot injuries of the head, as proved in many who were injured during the war. The author describes thirty-three cases of late posttraumatic epilepsy in which the latent period exceeded eight years. These cases of cranial injuries proved that as time advances, the manifestations of a hypersensitivity of the vascular nervous system, as symptom of a premature aging process, become more noticeable. The appearance of late epilepsy is preceded for a number of years by attacks of vertigo, which constantly increase up to the time of the first epileptic attack. The localization of the trauma seems to be of some importance, for twenty-one of the thirty-three patients observed by the author had had injuries of the frontal brain. The motor region, which seems to be of primary importance for early epilepsy, assumes only a minor role in the author's material. It was involved in only three of the cases. In five cases only the orbit had apparently been injured, but late epilepsy developed here too and it could be shown that the base of the frontal brain had also been injured, thus the cases of epilepsy could likewise be explained as posttraumatic.

- \*Peculiar Epidemic in Roskilde in December 1935 E J Henning—p 45  
 Agranulocytosis with Recovery After Liver Extract (Ereha) Parenterally Two Cases N R Christoffersen and E Polack—p 45

**Peculiar Epidemic in Roskilde in December 1935**—The disorder in Roskilde was characterized by sudden onset with nausea, vomiting, diarrhea, headache and dizziness, sometimes fever, brief duration (in three fourths of the cases forty-eight hours at the most) and lack of complications and of grave sequels. Some cases were mild, others violent. The epidemic developed rapidly, lasted about two and a half weeks and affected 40 per cent of the inhabitants, of all ages, in the district examined, the sexes seemed equally susceptible. In Henning's opinion the ailment is an independent infectious disorder readily transmitted by an unknown agent, and the various symptoms may depend on disturbances of certain parts of the nervous system. Rischel's "epidemic nausea" (Ugeskrift for Læger 97 12) [Dec 19] 1935) is believed to be identical.

## THE PROGNOSIS IN RENAL CARCINOMA

AND THE CLINICAL AND PATHOLOGIC DATA  
AFFECTING IT

WILLIAM F. BRAASCH, M.D.

AND

MILES GRIFFIN, M.D.

Fellow in Surgery the Mayo Foundation

ROCHESTER, MINN.

For the purpose of clinical consideration, malignant tumors of the kidney should be subdivided into two groups: those which have their origin in the renal cortex and those which arise from the renal pelvis.

In a survey of 283 patients subjected to nephrectomy for carcinoma of the renal cortex at the Mayo Clinic Judd and Hand<sup>1</sup> reported that seventy-four or 26 per cent, were alive and well at the end of five years. Although such favorable results may be influenced by operative technique, they probably are affected more by the histologic character of the tumor and by the extent to which the malignant process has progressed. A study of the pathologic and clinical factors conducive to longevity in these cases is of much clinical interest. What are the data derived from histologic examination of the tumor, and what are the data observed on physical examination or in the course of urographic visualization which influence the prognosis?

### PATHOLOGIC DATA

It is not generally recognized that tumors of the renal cortex are of common occurrence. Robertson<sup>2</sup> reported that, in routine studies of the kidney made at necropsy, some form of renal neoplasm is found in approximately 10 per cent of adult subjects. Most of these tumors are small, varying in size from 1 or 2 mm. to several centimeters. Although on section the histologic structure usually is described as benign, nevertheless such tumors are potentially malignant, and in some cases a lack of cellular differentiation is found which makes them actually so. Some of these tumors may become quite large and the cells may acquire a malignant character without producing any clinical manifestations. The histologic structure of renal neoplasms observed at operation is quite different and with few exceptions they give definite evidence of malignancy.

The prognosis in cases of carcinoma of the renal cortex is largely dependent on the degree of cellular differentiation, as suggested by Broders.<sup>3</sup> Although there are many variations in the morphologic charac-

teristics and arrangement of cells and in manner of growth of malignant tumors of the kidney, for practical purposes renal tumors should be regarded as just so many variations of renal carcinoma, and they should be graded in degree of malignancy according to the widely accepted criteria of cellular differentiation. This index was applied by Hand and Broders<sup>4</sup> in a study of tissue removed from 193 patients operated on for renal carcinoma at the clinic, with a degree of accuracy which proved its value in a striking manner. As might be expected, the average postoperative length of life was found to be distinctly longer in cases of tumors of the lower grades of malignancy, and only an occasional patient with a tumor of grade 4 was alive five years after nephrectomy. It was also found that the duration of preoperative symptoms was much longer in cases of tumors of grades 1 and 2, and that the duration diminished as the degree of malignancy increased. The importance of such gradations in determining the prognosis in cases of renal neoplasm is not fully appreciated.

Although from a prognostic standpoint all malignant tumors of the renal cortex may be regarded as carcinomas and may be graded according to evidence of malignancy, there are variations in the gross appearance and histologic structure which justify further classification. The most common form of cortical neoplasm observed is the adenocarcinoma, which is commonly called hypernephroma. Its gross appearance, color, apparently circumscribed localization and the papillary arrangement of its cells are quite distinctive. Adenocarcinomas may further be distinguished by the microscopic appearance of their cytoplasm which may be either clear or granular. A review by Foulds, Scholl and Braasch<sup>5</sup> of patients operated on for adenocarcinoma made up of clear cells revealed that the postoperative life of such patients was distinctly longer than when the cells were granular. Another form of renal carcinoma frequently observed has been called "alveolar" carcinoma. The gross appearance of these tumors is quite different and there is usually more diffuse involvement of the entire kidney. Microscopic examination shows that the character and arrangement of the cells are also different than in adenocarcinoma. Further differentiation between these two conditions is made possible by comparison of the clinical course as well as the urographic data. The slow growth and mild symptoms which usually characterize hypernephromas are in contrast to the clinical data observed in cases of alveolar carcinoma. Similarly the postoperative length of life of patients with the former type of lesion averages almost twice as long.

## CLINICAL DATA

Among the data observed on physical examination which should be of importance in affecting the prognosis in cases of renal carcinoma the following may be included the size of the tumor and the degree of fixation, evidence of toxemia, such as vascular changes, evidence of metastasis, and the data obtained by means of roentgenography. A consideration of these data combined with the conditions found at operation and the histologic study of renal tissue, should be of value in indicating the prognosis.

**Physical Examination**—A huge tumor with fixation should indicate a poor prognosis, whereas in the case of a small movable tumor the postoperative results should be better. Curiously enough, however, the postoperative course in cases in which tumors are large is often unusually good. It is of interest to note that in a group of twenty-four patients who lived ten years or more following nephrectomy, fourteen, or 58 per cent, of the tumors removed were recorded as large, four as medium, and six as small. However, in a group of forty-seven patients with inoperable growths, a fixed tumor was found in forty-four, and forty-two died within two years following exploration. The degree of fixation is apparently of greater prognostic importance than the size of the tumor. It is surprising how frequently a tumor of large size cannot be palpated, either because of its location under the ribs or because of a muscular or adipose abdominal wall.

The hematologic picture in cases of renal neoplasm is not distinct from that in cases of malignancy in other portions of the body. As with malignant conditions in general, a low value for hemoglobin usually indicates toxemia of malignancy and a poor prognosis. A renal tumor that has been present over a period of years without producing clinical evidence of toxemia will usually show on section a low grade of malignancy.

**Hypertension**—The frequency with which hypertension is observed in association with hypernephroma was first noted by Neusser<sup>6</sup> (recently referred to by Oppenheimer and Fishberg<sup>7</sup>), and he was under the impression that the hypertension was caused by absorption of some secretion from the tumor. He suggested that because of the possible suprarenal origin of such tumors they might be the source of tumor cells with suprarenal elements. Other observers have called attention to clinical evidence of abnormality in the vascular system which was apparently caused by some specific absorption. Telangiectasis of the superficial blood vessels of the face is frequently noted in cases of hypernephroma. Dilated blood vessels in the abdominal wall and varicocele of recent origin, usually on the left side, are observed frequently, probably being caused by mechanical obstruction of the venous circulation. An increased pulse rate was noted in several cases in which the temperature was normal and in which there was no evidence of infection. The possibility of fever occurring in cases of hypernephroma has been noted by Creevy.<sup>8</sup>

In reviewing the blood pressures of forty patients who were operated on for renal neoplasms in 1933 and 1934, it was found that the blood pressure was within

normal limits in twenty-six cases and was definitely increased in fourteen. In several cases the hypertension had apparently been present for several years prior to the onset of symptoms caused by renal tumor. Other clinical data noted would indicate that the hypertension was of the essential type. In those cases in which the blood pressure was read within a year after removal of the tumor, a definite decrease was noted in comparatively few of them, in most cases the blood pressure remained stationary. A recent clinical study by Horton and Morlock,<sup>9</sup> in which they compared the hypertension occurring in cases of hypernephroma with that in other forms of renal tumor, failed to show an increased incidence of hypertension in cases of hypernephroma or any difference in the postoperative reduction in blood pressure. Of the patients who lived five years after operation, four had systolic blood pressures of more than 200 mm of mercury. It is evident from these cases that hypertension does not materially affect the prognosis.

The possibility that renal adenocarcinomas might harbor elements of the adrenal gland which could be discovered on chemical examination of the tissue of the tumors was suggested independently by Ferguson,<sup>10</sup> by Beer<sup>11</sup> and by one of us (Braasch)<sup>12</sup>. In 1932 Kendall<sup>13</sup> examined two tumors but failed to find any evidence of adrenal secretion. Following his development of chemical methods of recognizing adrenal cortex secretion, he has examined three other renal adenocarcinomas but has likewise failed to find any definite evidence of adrenal secretion.

Although occasionally one gains the impression on clinical examination that renal adenocarcinoma is associated with hypertension of recent origin, it is evident from the postoperative clinical data and from chemical analysis of the tumor that no elements are present which would cause increased blood pressure.

**Metastasis**—Metastasis is common in cases of renal carcinoma and it must be carefully searched for in every case. It occurs less frequently in the case of growths of a low grade of malignancy, and then only in the late stages. Metastasis often is observed in cases in which symptoms are not suggestive of renal involvement or symptoms of recent origin. A review of the specimens removed from metastatic tissue for biopsy in most cases revealed carcinoma of grade 3 or 4. In Hand and Broders' series of 193 cases in which operations were performed at the clinic for renal carcinoma, evidence of metastasis was found in the course of preoperative and postoperative physical examination, at operation or at necropsy in ninety-eight cases. Although it is generally believed that renal carcinoma usually metastasizes through the blood stream, lymphatic metastasis was found in seventeen of these ninety-eight cases. The involved lymph nodes were found most frequently in the renal and retroperitoneal regions, and they were so situated that they could be demonstrated on physical examination in only three cases. Visceral metastasis occurred in fifty-six cases, the most common site of involvement being the lungs, followed in order of frequency by the liver, brain and spinal cord.

The site of metastasis in cases of renal carcinoma is so frequently in the lungs that thoracic roentgenography should be made a routine procedure in every case of

suspected renal neoplasm. In this way pulmonary metastasis frequently will be discovered in cases in which there are no pulmonary symptoms or any other clinical evidence to suggest it. On the other hand, early and minute pulmonary metastasis sufficient to cause mild symptoms suggestive of respiratory infection may be observed which is not apparent in roentgenograms made of the thorax. Cases occasionally are observed in which roentgenographic examination of the thorax was reported as negative and yet, at necropsy, made shortly after, metastasis is found in the lungs. When pulmonary metastasis does occur, it is usually found in both lungs. In the course of routine roentgenographic examination of the thorax, conditions are occasionally observed which may easily be confused with metastasis. Although the roentgenographic evidence of thoracic metastasis usually is quite definite, areas of consolidation are nevertheless sometimes observed in roentgenograms of the thorax which are of a doubtful nature, and a positive diagnosis may be of questionable value.

A number of recent articles have referred to the possibility of recovery from pulmonary metastasis. In fact, this possibility has been accepted in practice to such an extent that some surgeons have advised nephrectomy for renal carcinoma in spite of definite evidence of pulmonary metastasis. A review of six cases in which the patients were subjected to nephrectomy notwithstanding roentgenographic evidence of thoracic metastasis discloses that all the patients were reported to have died within one year following operation, and in most cases after several months. It is possible that in exceptional cases metastasis may be confined solely to the pulmonary region, however, this would occur so rarely that it is questionable whether one would be justified in advising nephrectomy in the presence of definite roentgenographic or clinical evidence of pulmonary metastasis.

Bony metastasis, generally believed to be of frequent occurrence, was found in but 11 per cent of Broders and Hand's cases. Because of its superficial localization it is observed more frequently in the course of general examination than other types of metastasis. The patient frequently has no symptoms suggestive of renal involvement. Although there was no predominant localization in the osseous system the more frequent involvement of the humerus and spinal column in this series is noteworthy.

Metastasis in the ureter was found in two cases in this series. Although of frequent occurrence in cases of epithelioma of the renal pelvis, it is rarely observed in association with cortical neoplasm. It is possible that hematuria, occasionally observed as a late post-operative complication following nephrectomy for renal carcinoma, may be caused by ureteral metastasis. Metastatic involvement of the suprarenal gland was found in two cases, in neither of which were there any symptoms or clinical data suggestive of suprarenal disease.

**Röntgenographic Data**—The value of the simple roentgenogram in the diagnosis of renal neoplasm is not fully appreciated. A careful survey of the renal regions in the simple roentgenogram frequently will give data of considerable importance. Unilateral increase in size or irregularity in the outline of the renal shadow should suggest the possibility of renal tumor. With accentuation of the renal outline such as occurs in the excretory urogram, these data may be of increased value. In the course of routine roent-

genography, the renal outline, unfortunately, may be so indefinite that the presence of abnormality is often overlooked.

The incidence of shadows in simple roentgenograms, caused by areas of calcification in the tissue of the tumor, is of much clinical interest. In a series of tumors of the renal cortex that were removed, roentgenographic evidence of calcification in the tumor was found in seven cases. It will be necessary to distinguish these shadows from those caused by lithiasis and from similar shadows frequently observed in cases of renal tuberculosis. The absence of any clinical, cystoscopic or urographic data suggestive of either lithiasis or tuberculosis usually would exclude these conditions. The deposit of calcium that occurs in cases of renal neoplasm is irregular in consistency and is usually confined to only one or two areas. In one case observed, however, calcification was widely scattered throughout the tissue of the tumor. It is of interest to note that, of the seven patients just mentioned, all but one lived more than three years and four were alive at the end of five years. It may be inferred, therefore, that the evidence of calcification is a favorable indication. The diagnosis of neoplasm frequently can be inferred in the presence of coincident areas of calcification in the simple roentgenogram and unipolar irregularity of the renal outline.

**Urography**—The value of the urogram in the diagnosis of renal neoplasm has long been recognized. However, with the development of urographic technique the standardization of interpretation, the discovery of innocuous mediums for visualization and particularly since the advent of excretory urography, it has become an essential and accurate method of diagnosis. The various types of deformity observed in the urogram in cases of renal neoplasm may be summarized as follows: (1) deformity characterized by tapering elongation or obliteration involving single or multiple calices, (2) partial or complete obliteration of the renal pelvis, (3) pyelectasis, with an irregularity in outline, and (4) displacement of the renal pelvis or upper segment of the ureter.

Involvement of but one or two calices, characterized by elongation and a tapering constriction of the terminal endings, is typical of hypernephroma and when present the diagnosis usually can be made. Irregular involvement of all the calices, a filling defect and partial obliteration of the lumen of the pelvis are suggestive of tumor of a high degree of malignancy, and these changes are more frequently observed in cases of alveolar carcinoma or epithelioma of the renal pelvis. Complete obliteration of the pelvis can easily be confused with a closed hydronephrosis. Minor degrees of deformity in the calices, such as crescentic flattening frequently observed with renal cyst and polycystic kidney, are sometimes found in cases of localized neoplasm. It has been claimed that clinical differentiation between simple cyst and renal neoplasm may be possible by observing the patient over a period of months for evidence of progressive change in the pelvic outline, such as might occur with neoplasm. The rate of growth of a hypernephroma, however, may be so slow that such differentiation is impossible. Because of the possibility of error in the clinical and urographic differentiation between renal cyst and neoplasm, surgical exploration usually is necessary.

In a recent review of 135 cases in which operation was performed for renal neoplasm it was found that

inaccurate interpretation of the urograms had been made in seventeen. In six, however, the diagnosis had been qualified as being either renal neoplasm or renal cyst, leaving eleven cases in which the diagnosis was definitely erroneous. A diagnosis of hypernephroma was made and simple cyst was found in two instances. A diagnosis of polycystic kidney was made in one case and it proved to be hypernephroma, in another case the diagnosis was reversed. Deformity in the urogram caused by cortical tumor and polycystic disease may be quite similar, and in doubtful cases the presence of abnormality in the pelvic outline of the second kidney usually will identify polycystic disease. In one urogram, made in a case of polycystic disease however, there was no evidence of deformity to be observed in the pyelogram made of the other kidney. In four cases the urogram suggested the presence of renal neoplasm and on surgical exploration the lesion was found to be extrarenal. Pressure and displacement from extrarenal tumor sometimes will cause abnormality in the outline of the pelvis suggestive of renal neoplasm. In one case the symptoms and apparent obliteration of the pelvic lumen suggested renal neoplasm, but on exploration a closed hydronephrosis was found. It may be difficult to identify the nature of an abdominal tumor when any visualization of the renal pelvis is impossible. The presence of shadows suggestive of calcification caused an incorrect diagnosis in two cases of hypernephroma. A circumscribed area of renal tuberculosis was found in one case in which there was little or no evidence of infection in the urinary tract. In another case exploration revealed a soft stone situated in the end of a calyx which had caused deformity of the pelvic outline suggestive of neoplasm.

**Excretory Urography**—The value of the excretory urogram in the diagnosis of renal neoplasm is not fully appreciated. It was first thought that its use in this field was limited and that a retrograde urogram usually would be necessary for accurate diagnosis. However, in thirty-five cases of renal tumor in which excretory urography was employed in the last two years we found that the evidence was sufficient to make a diagnosis in twenty-five. In the other ten cases it was necessary to make a retrograde pyelogram in order to secure adequate visualization of the deformity. Unless there is detailed visualization of the pelvis and calices in the excretory urogram it would be dangerous to assume that the possibility of renal tumor was excluded, and a retrograde urogram should be made. The increasing degree of accuracy in the recognition of renal neoplasm by means of excretory urography should warrant its routine employment in the differential diagnosis of abdominal tumors.

#### VALUE OF RADIOTHERAPY

Roentgen therapy in cases of renal neoplasm has been applied both before and after operation. Its value in postoperative treatment has not been very convincing. Although many of those patients who have lived three years and longer have had postoperative radiotherapy, the much larger number who have died within a year or two following operation in spite of radiotherapy makes the procedure of debatable value. In recent years, preoperative irradiation of the tumor has been urged by a number of observers. While our experience with such treatment has not been extensive, we have found it to be of greater value for tumors with tissue of embryonic origin than for adenocarcinomas.

It is of course necessary to wait two months following irradiation before surgical removal is attempted.

#### SUMMARY AND CONCLUSIONS

As an index to prognosis and in the interest of simplified terminology it would seem best to regard all malignant tumors of the renal cortex as carcinomas and to grade them according to the degree of cellular differentiation.

From a clinical point of view, carcinoma of the renal cortex may be divided further into two groups which have distinct clinical characteristics, namely, adenocarcinoma (hypernephroma) and alveolar carcinoma.

Although there may be various factors, such as metastasis, which can modify postoperative results, the prognosis usually will conform to the histologic evidence of malignancy.

Metastasis occurs most frequently with renal tumors of the higher grades of malignancy and may be present without causing clinical evidence. Lymphatic extension is a frequent occurrence. Metastasis is found most often in the lungs, rather infrequently in the osseous system. Although the progress of the disease in the presence of pulmonary metastasis may be delayed by nephrectomy and irradiation of the lungs, postoperative results indicate that the chance for recovery is so slight that operation is not justified. It is possible that the roentgenographic evidence of pulmonary metastasis in some of the few cases in which patients were reported as having recovered was incorrectly interpreted.

Calcification of tissues in cases of renal adenocarcinoma is a frequent occurrence and indicates a favorable prognosis. Urographic evidence of widespread involvement of all calices and of the pelvis indicates a high grade of malignancy and a guarded prognosis. The excretory urogram will give accurate information with regard to the presence of renal neoplasm in a high percentage of cases. Its routine use should be more frequent in the identification of abdominal tumors.

Although clinical data suggest that suprarenal elements may be included in some hypernephromas to account for the vascular manifestations such as hypertension and telangiectasis, neither chemical analysis of the tumors nor postoperative clinical data corroborate such an assumption.

While the size of the tumor alone has no bearing on the late postoperative results, nevertheless a large, fixed tumor, together with a short history and evidence of marked toxemia would indicate a bad prognosis and would accordingly render the advisability of operation questionable.

**Fuel Values of Foodstuffs**—The energy values of many of the proteins, fats and carbohydrates have been determined very accurately. Averaging the results for each group of foodstuffs, correcting in all cases for average losses in digestion, and in case of protein correcting further for the particular way in which it is burned in the body, we obtain the following physiological fuel values:

Carbohydrate	4 calories per gram	or 1 814 calories per pound
Fat	9 calories per gram	or 4 082 calories per pound
Protein	4 calories per gram	or 1 814 calories per pound

These values are intended to show the average amounts of energy actually made available to the body for each gram (or for each pound) of carbohydrate, fat and protein contained in the food. It will be noted that proteins and carbohydrates have, weight for weight, the same fuel value, while fat is a much more concentrated fuel, having two and one fourth times the energy value of an equal weight of protein or carbohydrate.—Sherman, H. C. Food and Health, New York, Macmillan Company, 1934.

## A SPECIAL FORM OF FUNCTIONAL PSYCHONEUROSES APPEARING IN AIRPLANE PILOTS

HARRY G. ARMSTRONG, M.D.

Captain, M. C. United States Army

DAYTON, OHIO

The clinical material on which this study was based consisted of 163 unselected airplane pilots. Their ages ranged from 22 to 50 years inclusive, their flying experience from one to eighteen years and their total flying time from 400 to 5,680 hours.

The data presented were derived from three principal sources, namely, close personal observation of each individual for from six months to three years, annual and semiannual physical examinations for flying, and professional attendance on all accidents and illnesses occurring in this group.

## HISTORICAL

Among pilots of all countries involved in the World War there was an enormous percentage invalided because of functional nervous disorders. Probably the best description of these cases was presented by H. Graeme Anderson<sup>1</sup> of England in 1919. Anderson recognized and described the various neuroses that occurred and they were admittedly no different from functional neuroses in other branches of the service or those found in civil life. Owing to the fact, however, that his cases developed as a result of flying he coined the term "aeroneurosis" and grouped all functional nervous disorders occurring in aviators under that heading.

The remaining authors of that period who described the same types of cases agreed with Anderson on the nature of these disease processes but coined various other descriptive terms, among the most prominent of which were "aeroasthenia,"<sup>2</sup> "flying stress," aviator's neurosthema" and "staleness."

It is believed that Anderson's term "aeroneurosis" (aero, combining form from the Greek *αἴρ*, *aeros* air + neurosis, from Greek *νεῦρον*, nerve) though applied here to a distinctly different type of entity from those he described, is the most appropriate and will be used in this paper.

## SYNONYMS

"Chronic fatigue," "staleness," "aviator's stomach," "flying stress," "aeroasthenia," "flying sickness," "aviator's neurosthema" and "fatigue" are synonyms.

## DEFINITION

"Aeroneurosis" is a chronic functional nervous disorder occurring in aviators, characterized by gastric distress, nervous irritability, fatigue of the higher voluntary mental centers, insomnia, emotional instability and increased motor activity.

## ETIOLOGY

**A. Predisposing Causes**—1. Sex. Only male pilots have been observed. It is believed, however, that under the same conditions females, being relatively more unstable, would be more frequently affected.

2. Age. Age as such, is probably not an important factor except indirectly. Since the stress of flying is one of the fundamental causes of the disorder, it follows that it cannot occur until flying training has been

completed, which is usually not under the age of 22. Even then, in my experience, there is an interval of years before the disease makes its appearance. In the series studied, the earliest case found was that of a pilot, aged 27, after four years of flying. From that age on, the incidence rapidly increased through the years of greatest stress and then gradually increased further in the upper age brackets, as shown in table 1.

The complete explanation of this age incidence is given later, and it will be merely noted that it depends principally on those economic, social and biologic changes that come about usually in the age period 25-40.

3. Build. All of the cases noted, except one, occurred in men of a medium or slender build. This, however, is of no significance, since it is a characteristic of the group that the conformations were predominantly of that same type.

4. Heredity. Strictly speaking, heredity is not a factor. By a process of rigid selection by trained examiners all candidates for flying training who show an unsatisfactory heredity are rejected. Furthermore, those who present a satisfactory family history but who for any reason do not possess a marked nervous stability are quickly detected in training and eliminated.

Relatively speaking, however, there is in every aviator some instability or otherwise he would be nothing more or less than a clod. On this basis it has been found that those with the greatest inherent instability are the most affected.

TABLE 1—Frequency of Occurrence by Age Groups

Age Groups	Total Number	Cases	Per Cent
22-29	135	4	3
30-39	20	10	50
40-49	7	4	57
50-59	1	0	0
Total	163	18	11.04

ing more or less than a clod. On this basis it has been found that those with the greatest inherent instability are the most affected.

5. Social Status. Since the group under consideration is by selection and occupation of the same general social status, it is impossible to do more than note this and to make comparisons within the group in which there are variations.

In this series all the men were above the average in intelligence, lived in comfortable surroundings and engaged in a highly dangerous occupation.

Of those affected four, or 18 per cent, were single, while eighteen, or 82 per cent were married. Of those married, three, or 17 per cent, had no children, while fifteen, or 83 per cent, had one or more.

Economically, there was sufficient income for the comforts of modern life. The fact that pay increased with years of service could not be particularly significant, owing to the fact that the expense of living increased in proportion to the increase in members of families.

6. Individual Personality. In all cases observed there were certain striking personality characteristics common to the group. As already mentioned, there was a relative instability as compared to unaffected individuals. They were without exception predominantly extravertive. Professionally they constituted the finest type of pilot, having a great amount of courage, alertness, energy and vitality.

Personally, they were intense, generous, warm hearted, friendly, devoted to duty and family and, in general, a high type of individual. Their actions were

<sup>1</sup> Anderson, H. G. *The Medical and Surgical Aspects of Aviation*. London: Oxford Medical Publications, 1919.

<sup>2</sup> Wells, H. V. *The Flying Service from a Medical Point of View*. Roy. Nav. Med. Service, 1, 55-60, 1915. *Some Airplane Injuries and Diseases with Notes on the Aviation Service*, ibid., 2, 65-71, 1916.

frank and vigorous, their feelings ruled the intellect more than good judgment, and their feelings were devoted to those about them

**B. Exciting Causes**—Under this heading are included those factors which are considered to be a cause of the actual breakdown. In addition, a brief consideration of two other factors is introduced here for the sake of completeness. The first one deals with the possibility of debilitating states as an exciting cause as so frequently happens in the other neuroses. The second one deals with a factor that may have some influence but, owing to the lack of clinical pathologic proof, it is mentioned only as a field for further research.

**1. Debilitating States** As might be expected, considering the close medical supervision and frequent physical examinations pilots are kept remarkably free from debilitating conditions. The use of intoxicating liquors and tobacco among those affected was similar to that among those unaffected and is not considered to be of any significance. Focal infections were carefully watched for and treated or removed immediately on detection. In this series, therefore, it is possible to state definitely that debilitating conditions were not an exciting factor.

TABLE 2—*Harmful Physical Agents and Their Effects*

Physical Agent	Primary Effect	Secondary Effect
Carbon monoxide poisoning	Anoxemia	Nerve tissue destruction
Oxygen want	Anoxemia	Nerve tissue destruction
Pure oxygen inhalation	Irritation, congestion and edema of lungs Irritative pneumonia	Anoxemia and nerve tissue destruction
Head trauma	Concussion, laceration, edema and hemorrhage of the brain	Nerve tissue destruction
Centrifugal and centripetal forces	Pressure, congestive edema, hemorrhage of brain	Nerve tissue destruction
Speed	Not known	Not known
Barometric pressure changes	Not known	Not known

**2. Physical Agents** I believe that the disease under discussion is partially an organic as well as a functional nerve disease. While there is strong presumptive evidence to this theory, it is deemed advisable to refrain from making definite statements until clinical or pathologic proof is available.

In table 2 is a list of the harmful physical agents to which pilots are frequently subjected and the primary and secondary effects. All the effects noted have been shown to occur under similar conditions of exposure, both by clinical pathologic observations in human beings and by animal experimentation.

**3. Emotional Stress** Emotional stress is considered the principal etiologic exciting factor. A review of the existing causes of emotional stress among pilots at once discloses their number and intensity.

**(a) Biologic Changes** Every normal human being passes through certain natural biologic phases of life which exert a marked influence on his behavior.

In youth man normally is possessed of an abundance of vitality and vigor, has a zest for adventure, shrinks from responsibilities, is fired by enthusiasm and shows a reckless courage born of inexperience. As youth passes, he grows more conservative, establishes a home, creates a family, assumes responsibility and girds himself for the struggles of self and race preservation and to acquire economic and social security.

He anticipates a slow but steady advancement in his chosen profession with a corresponding increase in

compensation until retirement or disability places him on the retired rolls.

Few pilots are able to pass through this normal course of events but are thwarted again and again by circumstances over which they have no control. How and why these normal biologic processes are disrupted will be shown in the discussion to follow.

**(b) Physiologic and Physical Changes** Regulations specify the physical qualifications for pilots. These qualifications are detailed and rigid and they demand almost perfect physical conditions for compliance. They serve as a guide in the selection of cadets for flying training and apply equally to the graduate pilot. The pilot of 60 is expected to qualify under the same standards as the lad of 20. Obviously, physiologic changes intervene which make it impossible for the older men to pass their physical examinations. Pilots early in their service begin to realize that their careers are in jeopardy. Every minor accident or disease is a potential source of flying disability, every minor physical defect a source of constant worry, which reaches its climax twice yearly at the annual and semiannual physical examinations.

It is true that waivers are normally granted for some of the minor defects, but this is considered only a stay of execution, a reprieve for a limited time only. It is not the wrecking of the career that we are concerned with here but the fear, the uncertainty, the social and economic insecurity which hangs, often for years, over the pilot's head and adds a heavy burden to his cares and depletes his nervous resistance.

**(c) Ego Deflation** The World War changed the status of airplane pilots from crazy fools to national heroes. The public changed its attitude from one of curiosity and scorn to one of honor and respect. Thus for the first years the military pilot had his ego tremendously stimulated. Gradually, however, aviation has become more commonplace. No longer do people rush out to see an airplane. Aviation has become an industry instead of an exhibition. Flying has become an occupation instead of a stunt. Aviators became human beings instead of gods.

This slow but definite change has deflated the pilot's ego and thereby created a further emotional stress. There is the constant attempt to regain face, to reclaim and hold a fading dream. It was this stimulated ego, which lasted for several years after the war, that accounts for the fact that "aeroneurosis" is of rather recent origin. It was, in a sense, the reward or compensation for the risk involved.

Another factor affecting the ego appears at about the age 30 to 40, or after about ten to fifteen years of flying. As is common in many pursuits, such as athletics, fliers reach their peak of efficiency early in life. Unlike the similar pursuits that are well established and in which a decline is anticipated early, aviation has no such precedent. Pilots anticipate aviation as a lifetime profession and the knowledge that finally younger and less experienced pilots are outperforming, outmaneuvering, outlasting and outdaring them is indeed a bitter blow to the once sustaining ego. Then again all those factors which are likely to result in the grounding of the pilot have their ego deflating influences. The grounding of a pilot carries with it a certain loss of caste or face, a partial loss of compensation, lower standards of living, social insecurity and, in general, a train of events which by their very nature depress the ego. Here again we are concerned only with the emotional stress engendered.

(d) *Economic and Social Security* Normally flying pay provides a sufficient income for the average individual as long as it continues, but any influence which jeopardizes that pay creates at once in that individual a marked sense of economic and social insecurity. This comes about by reason of the fact that, once established on flying pay, the average pilot makes certain commitments based on his anticipated income. Consequently, when his income is reduced, he necessarily must lower his standard of living, he loses a certain amount of professional and social caste, his ego is deflated, and he is left with no recompense for the added hazards of disability or death which he had successfully endured. The net result of his extra risks is to escape with heavy commitments on a reduced income at the time of life when most men anticipate an increased compensation and expect to be at the peak of their efficiency.

Normally the first change to direct the individual's attention to his uncertain economic position is the development of minor physical defects or deviations which suspend him temporarily from flying. It is then that he realizes the problem before him. No longer is physical perfection a gift of nature but a condition to be maintained with difficulty, if at all.

The second change that comes about is the added responsibilities assumed when a home is established and a family created. Here the relative conservatism of advancing age adds to the problem, for at this stage there is something more vital at stake. Not only must the individual provide for his own welfare but now there are others to be protected and provided for. The individual's instincts of self preservation may be repressed, his security may be ignored, but the responsibility to others is a duty which he faces with no attempt to repress or avoid but with a determination to provide an adequate solution. By their very natures these individuals are prone to be relatively immune from selfish personal natures, at the same time their consideration for others is developed to a marked degree.

(e) *Psychic Trauma* There are few occupations which so frequently subject those engaged to such marked subjective and objective psychic shock as does aviation. Few pilots pass many years without one or more serious airplane accidents. Whether or not there is physical injury, a crash always produces profound psychic trauma. The impact of a swiftly moving airplane with the ground or another airplane, in addition to the sudden deceleration, floods the nervous system with a deluge of efferent impulses and sensory impacts of terrific volume. The ultimate effect is not susceptible of objective analysis, but there can be no doubt as to the damaging effect to the whole nervous system.

In addition to being subjected to airplane crashes, pilots are frequently a witness to the crashes of others. Crashes undoubtedly produce the most violent known deaths, and rescuers usually find a mangled corpse with brain tissue spattered over the instrument board, naked bones projecting through flesh, and the body a jelly-like mass confined to shape only by the clothing. Frequently gallons of spilled gasoline turn the twisted mass of wreckage into a concentrated hell of searing flame while the victim writhes and curls amid the stench of burning flesh.

To witness one of these scenes is never to forget it. To witness one and fly one must forget it, repress it, and thereby a new conflict arises.

(f) *The Instinct of Self Preservation* The instinct of self preservation, being the most fundamental and deep seated of all instincts is capable of arousing the

most profound emotional disturbances. These emotional disturbances, other things being equal, are directly proportional to the degree of the hazard and the length of time endured. It does not require an actual hazard to produce these disturbances, but they are as readily produced by instinctive fears for which, in reality there is no basis.

(1) *Fear of loud noises* It has been found that loud noises are one of the two external agents which are capable of producing manifest fear in young infants. That this fear is instinctive and has a powerful effect on our reactions is demonstrated by the universal habit of every one jumping and showing a startled facial expression at any sudden unexpected loud noise despite the fact that no one has ever been injured by a noise.

It is therefore probable that aviators, subjected as they are to the extreme noises of high-powered unmuffled motors, have to repress this normal instinctive fear, which adds its load to the burden of the nervous system.

(2) *Fear of falling* Fear of falling is the second of the two external agencies capable of producing manifest fear in young infants. Added to the fact that it is an inherited instinct, it has for a background in most individuals, especially in childhood, a long painful series of experiences to prove its worth. Thus from experience and instinct all normal individuals have a marked fear of high places and of falling. It is this fear which to a great extent determines whether or not flying cadets complete their flying training. Those who are unable to suppress this fear are tense on the controls and never are able to fly well and are rejected. However, the repression of this fear does not in any sense relieve the nervous system of that burden but actually intensifies it as the conflict between desire and conduct rages in the unconscious.

(3) *Accident hazards* Aviation is recognized as a hazardous occupation. This hazard fluctuates from year to year but in general maintains a rather constant level. The improvement in materials and design are about equally offset by increased speed and performance. In the group under consideration there were for the three-year period ten deaths, one from natural causes and nine from airplane accidents. In other words, each day these pilots were nine times more apt to die from an aircraft accident than from natural causes. Furthermore, since the average flying time for the group was about thirty hours a month, or one hour a day, their hazard per hour while flying was nine times twenty-four hours (per day) or 216 times the hazard per hour while not flying.

In addition to the deaths, there were nineteen emergency parachute jumps, seven collisions in midair, and seventy-seven aircraft accidents of various degrees producing injuries to thirty-nine individuals.

Since the instinct of self preservation is the dominating influence of our existence, it is not difficult to realize the stress to which these pilots are constantly subjected. To carry on successfully they must repress this instinct into the unconscious, where it remains hidden from view but nevertheless constantly exerts its emotional influence.

(g) *Fatigue of the Brain Centers* The military pilot lives in an environment containing all the classic elements for incurring mental fatigue. Reviewing the psychologic causes of fatigue as quoted by others, the one common, all-important feature seems to be mental conflicts.

The concentration of attention required by his occupation is probably unsurpassed by any other. In addition to this, his mind is beset to an abnormal degree, consciously or unconsciously, with the following vital problems:

- Thwarted ambitions
- Biologic pattern distortion
- Disqualifying physiologic changes
- Disqualifying physical changes
- Disqualifying nervous and mental changes
- Ego deflation
- Economic insecurity
- Social insecurity
- Psychic trauma
- Self preservation

Not only do these various problems exist but to the average pilot they appear inevitable. The constant endeavor to make the proper adjustments is indeed a task to test the fiber of the strongest intellect.

#### SYMPTOMATOLOGY

All pilots are under constant observation by trained flight surgeons and are given a thorough physical examination at intervals of from one to six months. The first definite evidence of any defect whether physical or mental requires the grounding of that individual and the prompt administration of remedial measures. It is thus obvious that any disease process which is amenable to treatment is not allowed to progress through its natural course to a final termination. For this reason it is to be understood that the data presented here do not pretend to describe the disease process throughout its natural course but probably only its initial stages.

This close observation of pilots no doubt explains why an interval of years has passed before the accumulated data crystallized into the conception of new clinical entity. In my experience it was in pilots who had been on prolonged detached service away from proper supervision that the most advanced cases were observed and first gave a clue to the true nature of the disease.

#### CLINICAL HISTORY, MODE OF ONSET

Just when to fix the exact time of onset of this disease in most cases is extremely difficult, but it was noted that it invariably followed a period of unusually heavy flying.

The patient himself, at first being unaware of any nervous disorder, does not connect it with any definite date or event. It is probable that the change from normal is so gradual that the actual onset predates by several weeks or months the attention of the patient or the surgeon. A searching inquiry usually reveals the rather constant history of what is probably a recurring gastric neurosis, sometimes dating back for several years before the appearance of other symptoms.

#### SUBJECTIVE SYMPTOMS AND PHYSICAL CHANGES

As may be anticipated from the functional nature of the disease, symptoms may appear in any system of the body. In contradistinction to most functional disorders, however, this disease process exhibits rather remarkably uniform symptom patterns so far as they have been observed. It was noted that there were certain features common to all. The disorder was essentially subjective with no objective evidence of disease (except as noted later). There was evidence of irritable fatigue of the higher brain centers accompanied by increased motor activity. There was finally a disagreement between the symptoms complained of and the conduct of the patient, which further emphasizes the emotional nature of the disorder.

#### SYMPTOMS RELEIABLE TO THE CEREBROSPINAL NERVOUS SYSTEM

1 *Subjective Symptoms*—(a) *Mental State* The patient is restless and irritable, and his nerves are on edge. There is a tendency to resist the idea of illness but with usually a complaint of overstress and overwork. Everything and everybody acts as a source of irritation and in his home the family suffers from his pent-up feelings. The patient is apprehensive for the future and miserable in his environment, but he refers all this to conditions outside his body.

One of the most constant complaints is of insomnia or light and fitful sleep disturbed by unpleasant dreams or actual nightmares. The latter are occupational in character and usually concern flying with disastrous results. An unusual feature frequently found, which is probably a result of the dreams, is the extreme depression on awaking in the morning, with an accompanying profound dread and apprehension. For this reason patients appear most unwell in the early part of the day and improve during the afternoon until evening, when they regain a less depressed but more irritable mood.

There is some diminution of attention and difficulty of concentration. In most cases there is developed a mild paranoid personality, the patient feeling that he is being treated unjustly and that there are deliberate attempts to discriminate against him. This is especially true with regard to duties assigned and as a result there is a distaste for his occupation.

(b) *Projection Pathways* Since headaches are frequent among pilots from ill fitting goggles and helmets, carbon monoxide poisoning, anoxemia and blocked sinuses, it is rather difficult to evaluate this symptom. In my opinion it occurs more often than normally among these patients, especially in the morning, and is due principally to lack of adequate rest. There were no complaints of tenderness of the scalp or along the spine. Skin sensibility was normal with no complaints of numbness, tingling, heat, cold, sweating or anesthesia.

(c) *Eye Symptoms* Continued use of the eyes for reading often brought on rapid fatigue with burning and smarting of the conjunctiva and blurring of vision in bright lights. Often there was itching of the lids and a feeling of dryness of the eyeballs.

(d) *Ear Symptoms* All pilots after a few years' service acquire a variable diminution of hearing. This serves to diminish any hyperesthesia to sound and protects to some extent against auditory irritations. There seems to be a tendency for balance tests to show an increased unsteadiness, and whirling tests increase the nystagmus time and past-pointing.

(e) *Disturbances in the Organs of Smell and Taste* There were no symptoms elicited for these systems, although some patients reported a distaste for food.

(f) *Muscular System* Despite the frequent references in the literature to this syndrome as a chronic fatigue, as far as the voluntary musculature is concerned the opposite condition prevailed. Regardless of the loss of rest or mental weariness, there was always a ceaseless activity. A great amount of athletics was indulged in and mostly those of a strenuous nature. Movements were almost continuous and of a restless type and any activity was welcome. No complaints of unnatural muscle fatigue, cramps, tenderness, spasm or twitchings were noted. The one possible exception to this was the manifest deviation of the eyes as measured on the phorometer, and that this was of muscle and not nervous origin has not been proved.

2 *Physical Changes*—As may be expected, there were few objective symptoms demonstrated. At this point, however, it is wished to call attention again to the possibility that there might very well be considerable organic destruction. I have clearly demonstrated by animal experimentation that conditions to which pilots may be exposed can produce severe central nerve lesions. However, until this has been definitely supported by clinical pathologic observations it will be mentioned only as a field for further study.

(a) *Mental State* There was a peculiar analogy between the objective mental state of aeroneurosis and that seen in pneumonia (anoxemia). The mind was apprehensive, alert, anxious and restless. The subjective mental state was more apparent than real, for if called on the patient could by effort carry on normally.

(b) *Projection Pathways* The eyes were negative except for the apparent weakness of the extrinsic muscles. Examination of the eye and appendages during complaints of fatigue and irritations usually failed to show any abnormality. The field of vision and color remained normal as did the ocular fundi. There was often nystagmus in the lateral positions, however, and a coarse tremor of the closed lids.

*The Ear* Thickening of the membrana tympani could be accounted for as occupational. There were no other abnormalities.

*Smell and Taste* The nose was apt to show evidence of chronic irritation, but this was occupational and of no significance.

*Sensory Skin Disturbances* No cases of sensory skin disturbances were observed.

*Muscular System* Muscle sense and sense of position remained normal, with no ataxia, incoordination, hypertrophy or atrophy observed.

3 *Special Tests*—The tendon reflexes had a tendency to be somewhat exaggerated, but not routinely so. Corneal, pupillary and skin reflexes remained normal.

4 *Symptoms Referable to the Autonomic Nervous System*—It has been established by researches of Cannon and others that the emotions, acting through the sympathetic nervous system, have a profound effect on those organs supplied by that system. Furthermore, it has been found that these organs are affected in the order of their primitive origin, the gastro-intestinal being followed by the cardiovascular, respiratory and genito-urinary in order.

The reactions that take place are designed to place the organism in the best condition to defend and maintain life and are thus dynamic reactions, with every system mobilized and ready for instant combat.

This continual excess flow of energy constitutes a drain on the organism which it is impossible to replace and thereby a vicious circle is established, ultimately producing a breakdown of the normal functional processes without causing organic destruction.

5 *Subjective Symptoms and Physical Changes*—

(a) *Gastro-Intestinal System* The universal presence of gastric symptoms in "aeroneurosis" was a testimony to the intense emotional factors involved. While this symptom was the one most frequently complained of, it seldom was the cause of any great apprehension to the patient. Whether this was a result of the general knowledge that pilots are subject to "aviator's stomach" or to the fact that pilots were reluctant to divulge any defect that might jeopardize their flying is not known. By careful inquiry it was established that this was always the first subjective symptom recognized as such.

Gastric distress appeared from one to four years prior to the recognition of the fully established disease process and was a recurring episode brought forth by periods of hard flying, disappearing in between times only to reappear again. The complaints of gastric disturbances were remarkably constant and consisted essentially of a gnawing pain in the epigastrium not unlike the hunger pains of ulcer. There was no loss of appetite, nor were there complaints of nausea, vomiting, eructation of gas or distention.

Later in the course of the disease there developed a hypermotility of the intestine, with gurgling of the contents and sometimes a mild watery diarrhea. As might be expected, no organic changes in the gastro-intestinal tract could be demonstrated. The hypermotility of the stomach and intestine could readily be observed by means of the roentgenograph and the fluoroscope. Inspection of the stools showed a loose consistency in some cases with gross evidence of undigested particles of food material.

(b) *Cardiovascular System* There were no specific complaints regarding this system except occasionally a consciousness of the heart beat or throbbing of the carotids at night, although these were recognized as such and caused no undue apprehension.

The objective manifestations in the mild cases were approximately normal but in the few advanced cases observed it was noted that there was a comparative increase in the heart rate, a lowered diastolic and increased systolic blood pressure, lowered exercise tolerance and a tendency to neurocirculatory asthenia.

(c) *Respiratory System* In this system even the advanced cases showed no evidence of abnormality. Breathing rates and depths were normal and cyanosis was not observed.

(d) *The Genito-Urinary System* There were no complaints of this system and no variations from the normal were found. In keeping with the general increased activity it was found that there was a corresponding increase in sexual functions.

(e) *Laboratory Examinations* Blood counts and hemoglobin estimations were normal and presented no characteristic picture. Wassermann and Kahn reactions were negative. The urine was usually increased in amount and of low specific gravity. Casts, albumin and sugar were not normally found, and organic and inorganic compounds were present only in the usual amounts. The stools were usually normal but occasionally contained particles of undigested food, particularly the proteins.

#### DIAGNOSIS

The diagnosis of "aeroneurosis" in even a moderately advanced case is not difficult. That this is true is evidenced by the fact that it has been recognized as an entity by most authors even though there has never been a previous clinical description of the disease. A complete review of the current literature fails to show a single instance of the known functional nervous disorders being described in airplane pilots, while at the same time there has been a constant reference to this syndrome under an arbitrary designation which most nearly described it to the author.

The occurrence of a functional gastric disorder in pilots of several years' experience combined with a general irritability and increased motor activity with subjective complaints of insomnia and mental fatigue is usually sufficient for a tentative diagnosis. A positive diagnosis can be made only after ruling out the two following conditions:

1 *Distinction from Other Organic Disease*—In my cases the only organic diseases that might have caused any confusion were gastric and duodenal ulcer or tumor. These conditions should always be ruled out by gastric analysis and roentgen examination.

Exhausting and wasting diseases as well as intoxications and other debilitating conditions should cause no difficulty because of the increased activity in the cases of "aeroneuroses." Organic disease of the nervous system should be detected by proper physical examination and serologic tests.

2 *Distinction from Other Functional Nervous Diseases*—The essential differentiating factors in "aeroneurosis" from other functional nervous disorders are as follows:

In hysteria the personality is distinguished by an inborn instability with short explosive outbursts and a tendency to self-seeking satisfaction based on a complacent observation of the disability.

Neuresthenia is characterized by a motor fatigue, which is readily distinguished from the activity of "aeroneuroses."

Psychasthenia, of course, concentrates its symptoms on the psychic side and develops in an altogether different personality.

TABLE 3—Other Nervous and Mental Diseases

Disease	Number of Cases	Years of Service	Age at Onset
Neurasthenia	1	5	26
Anxiety neurosis	2	{6 months 2 years	{23 22
Hysteria	1	3	24
Hypochondria	1	3	26
Dementia praecox	1	0	21
Malingerer	1	4	26

The first stages of dementia praecox and cyclothymia may present some difficulties, but a period of observation should make the differential diagnosis simple.

#### COMPLICATIONS AND SEQUELAE

As explained under Symptomatology, the cases under consideration were treated early in the disease and not allowed to progress. No complications were observed and it is not believed that the condition is serious with regard to prospects of life. However, the effect is such that flying becomes dangerous and all such patients should be grounded.

*Association with Other Diseases*—While the group of cases under consideration here were free from other diseases and maintained in otherwise excellent health, there is no reason to believe that they could not be associated with other disease processes. It is especially likely that focal infections or other debilitating disease could act as an exciting factor.

It is interesting to note that those individuals who suffered from other nervous and mental disorders were entirely free from symptoms of "aeroneurosis" and all developed earlier in time both as to age and service. The other nervous and mental cases and the number of each in the observed group of 163 are given in table 3.

#### CLINICAL VARIETIES

No clinical varieties of the disease could be distinguished. In view of the fact that this is a functional nervous disorder the uniformity of the symptoms and other manifestations is rather remarkable. It might well be that cases allowed to progress would finally show considerable variation, but until that has been observed this remains pure speculation.

#### TREATMENT

1 *Prophylaxis*—"Aeroneurosis" could probably be eliminated by a careful selection of candidates for flying training. The personalities and characteristics of those susceptible having been determined, it is believed that they are susceptible of identification and elimination at the time of application for examination.

This simple expedient, however, has the distinct disadvantage of depriving aviation of those who are acknowledged to be the highest type pilots. The problem resolves itself into a question of whether it is more desirable to select the better pilots who break down after ten or fifteen years' service or poorer ones who are more durable.

Assuming that it is highly desirable to retain the better type of pilot, it becomes necessary to determine and remove the causative factors in aeroneurosis. As already noted, the principal causative factor was profound emotional stress produced principally by accident hazards and social and economic security. The former is an inherent characteristic of aviation and in the present state of our knowledge is not amenable to regulation. The latter, while not under the control of the medical profession, is a direct responsibility of the medical profession and as such should be subject to proper regulation for the protection of the individual and of the flying public.

Hershey,<sup>3</sup> in discussing the treatment of functional neuroses, says "The first step in the treatment of these cases consists of discovering the cause of the conflict. If the conflict is based on a real situation which does in fact jeopardize the social or economic security or arouses the instinct of self preservation then, while it may be possible to temporarily get the patient symptom free, it is never possible to get a permanent cure until the cause of the conflict has been removed or has been adequately compensated for." This finding, based on an extensive clinical experience is further borne out by Wright,<sup>4</sup> who has found that "among a large series of commercial pilots nervous disorders are infrequent among pilots who receive an adequate income and almost all cases that have developed were observed in those individuals who received inadequate compensation for the hazards endured or whose positions, and consequently their economic state, were insecure."

From the foregoing and my experiences with "stunt" pilots, it is well established that the emotional stress of flying hazards can be offset by suitable compensation, either ego stimulating or monetary. Since modern commercial aviation lacks any great amount of ego stimulation, it remains to establish some standard to determine at approximately what point compensation overcomes the effect of the accident hazard.

For the group under consideration, it has already been noted that, as compared to ground personnel, where the hazard is 9 to 1 the compensation is 15 to 1. In Wright's<sup>4</sup> series of cases it was found that, when the compensation was between 2 and 3 to 1, no difficulty was experienced. Therefore it may be assumed that flying pay equal to three times the normal for equivalent ground personnel is adequate where the fatality rate is nine times as great. Expressed mathematically:

$$\text{Flying pay} = \frac{\text{Flying hazard}}{3} \times \text{ground pay}$$

The economic and social insecurity among aviators seems to be due principally to the fact that usually during middle life, when their social and family respon-

<sup>3</sup> Hershey, Lynn. Personal communication to the author.  
<sup>4</sup> Wright, H. B. Personal communication to the author.

bilities are the heaviest, they are removed from flying and forced to accept a minor ground position on greatly reduced pay. Whether or not this actually happens is of no great importance, since it is the years of uncertainty preceding this period that produces the emotional stress and hence the nervous disorder. To create for these individuals a proper economic security, nothing would appear more reasonable and effective than a modification of the present system employed in any other occupational disability. The pilot who is grounded from flying but otherwise fit should be given a flying disability retirement and allowed to assume an executive or administrative ground position. It is believed that this plan, in conjunction with adequate pay for the risks involved, would allow the majority of pilots to pass through their flying career free from aeroneuroses.

In actual practice, the prophylactic measures adopted were those calculated to provide for good health, pleasant environments and active recreations. Special attention was devoted to the elimination of all possible sources of mental irritation and worry.

**2 Active Treatment**—In the active treatment of the cases considered here, all the usual measures were given a fair trial. Diets, rest, hydrotherapy and various psychoanalytic maneuvers were all of no apparent benefit. Complete removal from the environment in some cases produced marked temporary improvement provided it involved no economic loss to the individual, in which event no improvement or an aggravation occurred. In those cases in which an improvement did occur it proved to be only temporary, for after three months' to a year's duty the attack invariably recurred, usually more severe than the one preceding. It is from this experience that prophylactic rather than curative measures are considered to be of paramount importance.

**3 Final Disposition**—Based on the inadequate and unsatisfactory methods of treatment available to the group discussed here, four of the eighteen original patients have been removed permanently from flying, one by death in an aircraft accident, one by retirement for physical disability and two because of aeroneurosis. Of the fourteen still on flying duty, three are considered ready for retirement as totally permanently disabled, four are considered unfit for flying duty but fit for ground duty, and the remaining seven are considered able to remain on flying duty under close supervision.

The controlling factor in the final disposition of these cases should be the welfare of the individual and the protection of the flying public. Those who have had several recurrences, each more severe than the preceding one, and who are reduced to a state of unfitness for administrative duties should be permanently retired. Those who have had several recurrences and are kept symptom free only by grounding should be permanently grounded. Those who have no more than the initial symptoms, have had no more than one fully developed attack, or who have recovered from an attack and remained symptom free during a six months period of flying should remain on flying only under the close continuous observation of a surgeon.

#### PATHOLOGY

Whether or not actual organic nerve lesions can be demonstrated in cases of 'aeroneurosis' must for the present remain pure speculation. That this important aspect has not been fully investigated is due to the difficulty in securing suitable tissue sections. In the

crash cases examined, the trauma had so disorganized the brain tissues that the detection of other old lesions was found impracticable. As mentioned before however, experimental animals exposed to conditions similar to those endured by pilots have shown in many instances congestion, edema, hemorrhage, and even destruction of brain tissue.<sup>5</sup> These lesions were those normally found in cases of accidental death in man from the same physical agents and varied only in degree. The particular pathologic condition in each instance was dependent on whether anoxemia, carbon monoxide poisoning, trauma or centrifugal force was used and the lesions produced are too well known to require repeating here.

In any event, since the presence of actual pathologic changes could only be one of the contributing factors in this disease process the question will be left for future investigations to answer and I shall proceed to a discussion of the pathogenesis.

In considering the possible theories to explain the pathogenesis of "aeroneurosis," one is at once struck by the number of those which can unquestionably be discarded. Focal infections, wasting disease, debilitating states, exhausting fevers, toxins, intoxications, inferior constitutional states, hereditary taints, defective mentality and emotional instability can be eliminated immediately. There remains then only a psychogenic theory to explain the relationship between the etiology and the symptomatology. Therefore I will briefly reconstruct again the situation as it normally develops and trace by logical steps the mechanism of the defense reactions and on through the development of the disease process.

When an individual enters on his career as a pilot he is essentially physically perfect, with a high degree of intelligence, filled with ambition, possessed of great natural courage, fired with enthusiasm and devoted to duty. The irresponsibility of youth, the pride of accomplishment, the zest of living and the ignorance of inexperience carry him blithely through the first few years. Gradually, however, as time passes physical perfection is replaced by physical defect and physiologic change, ambition by apprehension, reckless courage by cool judgment, irresponsibility by responsibility, youth by age, inexperience by experience, and pride by ego deflation. In other words, there has been created a situation in which instinctive desires conflict absolutely with social regulation.

Primarily there is the powerful instinct of self preservation buried in the unconscious which strives to project itself into the conscious. This conflict rages continuously and, unbeknown to the individual, produces deep emotional reactions. Even though he is protected from mental pain by this repressed emotion, which allows him to carry on free from conscious fear, there is in this situation much material for intellectual insult. A simple comparison of the ratio between the accident hazard and the monetary compensation with regard to either commercial fliers or officers of the services offers nothing to the individual but the obvious conclusion that his worth is lightly valued. The accompanying ego deflation, resentment and sense of injustice add their burden of emotional stress. The higher the intelligence, the more this holds true. The high type appreciates the value of safety, the moron is unconcerned.

The many avenues of escape from this situation are naturally obvious to the individual but to this person-

ality type the price is too high To quit is unthinkable, to avoid the issue spells weakness, to accept emotional subjective equivalents of disease is to admit instability, and to shrink from responsibility is to invite social and economic insecurity

The latter, the almost inevitable social and economic insecurity, also is a situation capable of arousing great emotional disturbances To a great extent economic security or advantage relieves other stresses and acts as a prophylaxis against breakdowns Even fear may be overcome by adequate compensation, either monetary or ego stimulating, acting to repair the insult to the nervous system The lack of it only adds to the insult and further depletes the nervous mechanism This situation offers no certain means of escape and the anticipation may for years produce a deep anxiety and apprehension not only for the individual's own welfare but on account of all those dependent on him

The third situation calculated to produce a conflict between instinctive desires and social regulation consists of all those factors which concern the individual temperament These are principally the thwarted ambitions, ego deflation, loss of caste and all those items of importance to the proper maintenance of self esteem, high morale, mental peace and nervous stability

Thus these individuals are beset with a myriad of profound emotional stresses, some repressed, some clear to the intellect, all capable of producing marked reactions It remains then to show by what mechanism these forces are responsible for the symptoms produced

As noted before, it was first shown by Cannon and others that the emotions are capable of producing marked physiologic reactions This process is an inherited characteristic which comes into action whenever the maintenance or defense of life is endangered It occurs as a function of the sympathetic nervous system, which, when affected by the various unpleasant emotions, mobilizes the bodily resources as a means of preparing for combat or flight Each system of the body maintains itself at its highest pitch of efficiency to contribute its share in the defense of the organism The heart speeds up and the blood pressure rises to nourish the tissues better The respiratory apparatus increases the lung ventilation to supply a rich oxygen mixture to the blood The gastro-intestinal tract becomes hyperactive to prepare food for the body utilization The brain and nervous system stand alert and ready, actively guiding the maneuvers of the battle and acting for long periods without adequate rest, facing the situation squarely and striving for an adequate solution to the problem As long as the stress continues, the outpouring of the excessive energy goes on and the normal processes of conservation and repair are abandoned Eventually the physiologic reactions are brought to the attention of the individual and can be observed and measured by objective methods The nervous reactions are those of depletion of the higher centers Both reactions are free from the deviations of somatic or nervous defect, for in these cases there are no doubts and hesitation as in psychasthenia, no quitting under the guise of organic disability as in neurasthenia no infantile reactions of hysteria, or none of the obsessions or mental inamias of the anxiety states The victim stands firm and immovable but is worn down by irresistible forces In brief, the pathogenesis of 'aeroneurosis' consists of profound emotional disturbances, long continued, producing manifest hyperactive physiologic responses and higher nerve center depletion, the latter unaccompanied by abnormal deviations

## CONCLUSIONS

From a study of the functional nervous disorders occurring in 163 unselected airplane pilots over a period of three years, it is concluded that

1 Of the group studied 11.04 per cent suffered from a special form of the psychoneuroses, which affected 3 per cent of those in the age group 22-29, 50 per cent of those in the age group 30-39, and 57 per cent of those in the age group 40-49

2 The disease is a chronic functional nervous disorder, classifiable as a new type of the psychoneuroses A distinctive nomenclature being required, the term "aeroneurosis" is suggested

3 The principal etiologic factors are accident hazards, economic and social insecurity, and possibly nerve tissue destruction

4 The cardinal symptoms are general irritability, gastric neuroses, insomnia, motor hyperactivity, and depletion of the higher mental centers

5 Adequate treatment requires, in addition to the usual therapeutic measures, administrative changes to provide adequate compensations and economic and social security

6 The pathogenesis consists of profound emotional stresses, long continued, producing a physiologic hyperactivity and a depletion of the higher nervous centers

Wright Field

## SCARLET FEVER IMMUNIZATION DURING A SCHOOL EPIDEMIC

HAROLD S. DIEHL, M.D.

AND

ROBERT G. HINCKLEY, M.D.

MINNEAPOLIS

During the winter of 1935 an epidemic of scarlet fever occurred among the students of the School of Agriculture, in which we reported an epidemic of scarlet fever thirteen years ago.<sup>1</sup> The enrolment of the school at the time of this recent epidemic was 317 boys and 119 girls, practically all of whom lived in dormitories on the campus. The first case of scarlet fever appeared on January 15. The usual control measures were immediately applied, but the disease continued to spread. In view of this it was decided to resort to immunization in the hope of controlling the epidemic. Active immunization was employed on a large scale and passive immunization in a few individuals. The results of the passive immunization were discouraging but the occurrence of new cases of scarlet fever declined abruptly after the third dose of scarlet fever toxin had been administered to those who were susceptible.

Conditions in this school are unusually favorable for the spread of communicable diseases. The students, mostly of high school age, come from rural communities, live under rather congested conditions, congregate in one another's rooms, and have not been accustomed to obtain medical care for minor illnesses. The result is that certain students with mild infections remain up and about, in intimate association with a highly susceptible group of their fellows.

This outbreak of scarlet fever was preceded by an epidemic of German measles and numerous cases of

From the Students Health Service and the Department of Preventive Medicine and Public Health, University of Minnesota.  
1. Diehl, H. S., and Shepard, W. P. A Scarlet Fever Epidemic in an Agricultural School. J. A. M. A. 79: 2079-2085 (Dec. 16) 1927.

sore throat, clinically of the streptococcic type. This raised some difficult problems of diagnosis particularly as the cases of sore throat, possibly of the scarlet fever type, continued with greater or less frequency throughout the epidemic.

The first case of scarlet fever was diagnosed on January 15. Despite the daily examination of close contacts and the isolation and observation of suspected individuals, a second case with no known exposure to the first one, appeared on January 31. Both patients were boys and the infections were severe. From then on new cases kept appearing at intervals of one to seven days till a total of thirty-three cases had occurred, as shown in the chart.

#### THROAT CULTURES

Early in the epidemic, routine inspections of the throats of contacts were supplemented by cultures from the throats of suspected cases and contacts. Thirty-seven such cultures were examined for hemolytic streptococci in the laboratory of the University Hospital. Thirty of these were reported to contain many hemolytic streptococci; five showed a few colonies, and only three contained no hemolytic streptococci (table 1). Although all the individuals from whom these cultures were taken had positive Dick tests and were closely observed, none developed scarlet fever during the period of this epidemic. One individual in the group developed frank rheumatic fever and two developed sore throat with otitis media.

Cultures were taken also from three patients with scarlet fever and from twenty-one students selected at random from the group with positive Dick tests but without symptoms. These cultures were examined by the laboratories of the state board of health, according to the technic described by Tunnichiff.<sup>2</sup> The results are reported on the basis of the phagocytic index (table 2).

In a series of scarlet fever carriers reported by Tunnichiff, the phagocytic index varied from 4 to 18. Two of the frank cases of scarlet fever in our series (1 and 3) had indexes above 4 but the third case (2)

had a phagocytic index of only 0.7. Seven of the individuals included in the random sample of those with positive Dick tests had indexes above 4. Two of these (6 and 16) developed scarlet fever. One (19) developed rheumatic fever. The others showed no symptoms or signs of infection.

#### ACTIVE IMMUNIZATION

In view of the evident ineffectiveness of the control measures employed it was decided on February 12 to administer scarlet fever toxin to those susceptible who would not refuse it. Preparation for this was made by means of talks and bulletins to the student body.

TABLE 1—Cultures of Contacts and Suspects

Laboratory Report	Number of Cases	Per Cent
Many colonies of hemolytic streptococci	29	78
Few colonies of hemolytic streptococci	5	14
No colonies of hemolytic streptococci	3	8

22	1.2
23	1.4
24	1.6

A preliminary Dick test of the group showed that 59 per cent of the boys and 62 per cent of the girls were susceptible. Some of these had been previously tested and a few immunized. At the time of the reading of these Dick tests, temperatures were "taken" and inspections of the pharynx and skin were made. Those with any suspicious manifestations were isolated.

Two hundred and forty-one students were given the first injection of scarlet fever toxin, 500 skin test doses, February 17. Subsequent injections were given at weekly intervals, but owing to reactions and other disturbing factors the number injected decreased somewhat with each subsequent injection. If a severe reaction followed one dose, the succeeding dose was divided. This accounts for the fact that some of the individuals who were given five doses received less than the usual 135,000 skin test doses of toxin.

#### SUBSEQUENT COURSE OF THE EPIDEMIC

The occurrence of new cases by weekly intervals and in relation to the administration of toxin is shown in the chart. From this it is apparent that the number of new cases declined abruptly after the third dose of toxin. In fact only one new case developed between the administration of the third and fourth doses and two between the fourth and fifth doses.

It is possible, of course, that this decline may have been merely coincidental with and entirely independent of the administration of toxin. On the other hand, reports indicate that considerable immunity develops after three doses of scarlet fever toxin. Furthermore, the course of the epidemic was distinctly upward at the time of the administration of the toxin and except

<sup>2</sup> Tunnichiff, Ruth and Crooks, C. T. The Health Carrier in Scarlet Fever. J. A. M. A. 92: 1498 (May 4) 1929.

for the immunization there should have been a sufficient number of susceptible students left in the group to permit the epidemic to continue for a considerable period. In an epidemic of scarlet fever in Berea College in Kentucky, in which active immunization was employed, fifty-nine new cases developed between the first and second dose of toxin, four between the second and the third dose, and none after the third dose had been administered.<sup>3</sup>

#### REACTIONS TO THE SCARLET FEVER TOXIN

A considerable proportion of the individuals who received the scarlet fever toxin experienced reactions more or less severe, following the injection. Most of these reactions were not incapacitating but almost 5 per cent of the group had reactions after each dose severe enough to cause them to be admitted to the Health Service infirmary. The rashes that followed some of the toxin injections introduced a problem of diagnosis, which in certain cases was distinctly troublesome.

The frequency and severity of these reactions were in marked contrast to our experience with active immunization in the students of the same school in the fall of 1935. At this time sixty-two new students who reacted positively to the Dick test were given five doses of scarlet fever toxin and only two in the whole series had reactions severe enough to cause admission to the infirmary, and even mild reactions were rare.

#### IMMUNITY PRODUCED

Although it is always desirable to administer Dick tests after the scarlet fever immunization, it was impossible to do so in this group because of the end of the school term. However, eighty-three of the students who had received scarlet fever toxin during the epidemic were tested when they returned to school in October, approximately six months after the completion of immunization. Of these, 67 per cent of those who received less than 11,000 units of toxin and 93 per cent who received more than 11,000 units of toxin had negative Dick tests (table 3).<sup>3a</sup>

TABLE 3—Dick Tests Six Months After Scarlet Fever Toxin

Skin Test Doses of Toxin Administered								
Dick Test	500-1000		11 500-135 000		More Than 135 000		Total	
	Num ber	Per Cent	Num ber	Per Cent	Num ber	Per Cent	Num ber	Per Cent
+	9	33.3	4	7.4			13	15.7
—	18	66.7	50	92.6	2	100.0	70	84.3
	27	100.0	54	100.0	2	100.0	83	100.0

The results shown in this table indicate a highly satisfactory degree of immunization, but it is also interesting to note that during the epidemic no cases of scarlet fever occurred among forty-three employees who had positive Dick tests and were closely associated with the school students but received no immunization, and that when twenty-three of these were retested in October, nine, or 38 per cent, had negative Dick tests.

#### SCARLET FEVER ANTITOXIN PROPHYLACTICALLY

At the beginning of the immunization procedures scarlet fever antitoxin was administered prophylactically to twenty-five individuals who had positive Dick tests and had been in close contact with patients with scarlet fever. No antitoxin was administered to any who gave a history of allergy or to any who reacted to an intradermal test dose of the serum. Thirteen of the group were given 2,000 units of antitoxin in a single

dose, nine received two doses of 1,000 units each on subsequent days, and three received one dose of 1,000 units.

In spite of the precautions taken to avoid allergic reactions, nineteen, or 76 per cent of the group, experienced either immediate or delayed reactions to the serum, and seventeen, or 68 per cent, had moderately severe or very severe reactions. Several of these were distinctly alarming. This high proportion of severe serum reactions was surprising in view of the recommendations for its use in susceptible persons who have been exposed to scarlet fever<sup>4</sup> and the adoption of its use as a routine procedure for all Dick positive children admitted to the pediatric service of the Toronto General Hospital.<sup>5</sup>

Five of the group who were given antitoxin prophylactically developed scarlet fever, but three of these had received only 1,000 units of antitoxin. One who was given 2,000 units developed clinical scarlet fever within twenty-four hours from the time that the antitoxin was administered. In view of this experience, the use of antitoxin prophylactically was not continued.

#### SCARLET FEVER ANTITOXIN THERAPEUTICALLY

Scarlet fever antitoxin was used for the treatment of the more severe cases. Fifteen per cent of those who were given antitoxin had serious complications as compared to 35 per cent of those who received no antitoxin, and in the latter group there was one death. This occurred in a student in whom pneumonia and empyema developed after several days of mild illness. Although the number of cases treated in this series is too small to justify the drawing of conclusions, the results have caused us to adopt the policy recommended by others<sup>6</sup> of giving antitoxin to all patients with scarlet fever as soon as a diagnosis is made. Only one patient who received scarlet fever antitoxin for treatment had a serum reaction.

3a. During the current school year with scarlet fever again prevalent in the community five cases occurred among the students of this school. All of these were new students this year. Two were recorded as having had negative reactions to the Dick test on admission; one had just completed the series of five injections of scarlet fever toxin but had not had a subsequent Dick test; and two had had positive Dick tests in October but refused immunization.

## SUMMARY

1 Active and passive immunization procedures were utilized in an attempt to control an epidemic of scarlet fever among 436 students of an agricultural school

2 The number of new cases of scarlet fever declined abruptly after the administration of the third dose of scarlet fever toxin

3 A large proportion of the individuals had mild reactions to the toxin and approximately 5 per cent of the group were admitted to the infirmary after each injection. These reactions were of short duration and not serious, but when accompanied by a rash they introduced difficulties of diagnosis

4 Ninety-three per cent of a group of susceptible students who had received more than 11,000 skin test doses of scarlet fever toxin showed negative Dick tests six months later. Thirty-eight per cent of twenty-three other individuals who had had positive Dick tests at the time of the epidemic but received no toxin gave negative tests six months later

5 Scarlet fever antitoxin was administered prophylactically to twenty-five susceptible individuals who had been in close contact with patients with scarlet fever. Seventy-six per cent of these had serum reactions and 68 per cent moderately severe or very severe reactions. Five of the group who received scarlet fever antitoxin prophylactically developed scarlet fever

6 The results obtained with scarlet fever antitoxin for patients were satisfactory in this small series of patients

PARATHYROID A NEW ANATOMIC  
CONCEPT

CLINTON S. HERRMAN, M.D.  
PHILADELPHIA

The human body has been so carefully dissected and minutely studied that it is indeed an anatomic rarity for any one to claim a new observation. A perusal of the literature, however, failed to reveal the following which I am therefore reporting as original observations: 1 An explanation of the variation in the number of parathyroid glands found in any given specimen. 2 A description of the parathyroid nerves. 3 A location that may be considered normal for the inferior parathyroid gland.

The parathyroid bodies were first described by Sandstrom<sup>1</sup> in 1880. MacCallum,<sup>2</sup> Halsted<sup>3</sup> and others have added greatly to the store of knowledge concerning them. Their importance has been stressed in relation to thyroid surgery for years and total ablation of the thyroid gland has made the profession more parathyroid conscious. Lately, because of the recognition of parathyroid anomalies, the glands themselves have taken on renewed importance.

Textbooks and current literature all speak of the variability in their number and location, describe the arterial supply from the inferior and sometimes superior thyroid artery, and carefully omit mention of the nerve supply. Hembach<sup>4</sup> and others have attempted to chart

their number and location with little success. Feeling that such a variability in location was not in accord with the anatomic arrangement of any structure in the human body, my associates and I undertook this study. It is based on the dissection of thirty cadavers in the anatomic laboratory and several fresh specimens in the autopsy room. Each specimen was subjected to histologic study, and only those which proved to be parathyroids were considered. Ginsburg<sup>5</sup> has called attention to the deceptive character of lymphoid tissue in this region. We were deceived not only by lymph nodes but also by thyroid tissue and even by adipose tissue. These errors have been discarded in forming our conclusions. Our skill in recognizing parathyroids improved with each dissection and the incidence of error decreased as the series progressed. While our original intention was to study only the inferior parathyroids with the aim of finding their definite location, we became interested in the superior group and have

Fig 1—Artist's sketch of dissection by the author showing inferior parathyroid in ectopic position, superior parathyroid in position frequently found. Superior and inferior parathyroid stalk with nerves and arteries shown. Note the two glands derived from the superior stalk.

incorporated some of our observations concerning them. A more detailed study of the upper group will be made and reported at a later date.

## VARIATION IN NUMBER OF PARATHYROID GLANDS

On each side of the neck a branch of the inferior thyroid artery joins with a branch of the recurrent laryngeal nerve to form a 'stalk' to the parathyroid gland. Similarly a branch from the superior thyroid artery is joined by a branch from the superior laryngeal nerve to form a stalk to the superior parathyroid gland (fig 1). These four stalks are constant in number regardless of the number of parathyroids. Each of these four stalks described may lead to a single gland and that individual would have four parathyroid bodies. On the other hand from any of these four stalks two or more parathyroids may arise (figs 1 and 3). It is in this manner that the number of

From the Department of Anatomy, Temple University School of Medicine. This study was made possible through the kind cooperation of Professor John B. Lohdy.

parathyroids varies in different individuals Churchill<sup>7</sup> and others report parathyroid tumors in the mediastinum. One of our dissections illustrated in figure 3 showed the stalk giving off two parathyroids and continuing down beneath the sternum into the mediastinal space and fusing with the fibrous tissue over the

Fig. 2—Normal location of the inferior parathyroid gland. Note that it is free from the thyroid gland at point of crossing of inferior thyroid artery and recurrent laryngeal nerve. Note the short stalk formed by the artery and nerve to the parathyroid gland and the close position of the thyroid vein.

thymus. It could readily explain a mediastinal parathyroid. Lahey<sup>8</sup> and others have described parathyroids embedded in the thyroid gland. While in our dissections we did not encounter any, their presence can easily be accounted for according to our theory by the ingrowth of the inferior thyroid artery carrying with it the stalk of the parathyroid.

#### PARATHYROID NERVES

There is a definite nerve given off by the recurrent laryngeal nerve at the point at which it crosses the main branch of the inferior thyroid artery. This inferior parathyroid nerve accompanies the parathyroid artery and enters the hilus of the inferior parathyroid gland. It appears to supply no other structure. As every one knows, the superior laryngeal branch of the vagus divides into an internal and an external branch. The external branch, which is much the smaller, passes downward to supply the cricothyroid muscle. From this external branch a fine filament passes downward as the superior parathyroid nerve (fig. 1) and joins the company of the superior parathyroid artery.

We could find no description of these important parathyroid nerves. Maiman<sup>9</sup> carried out experiments on dogs to show that the vagus supplied the thyroid and parathyroid glands but gave no description of the nerves. Since such vital glands as the parathyroids derive their nerve supply so directly from such a highly specialized nerve mechanism as the nerves supplying the larynx, it might not be amiss to conjecture for a moment on the possibility of the physiologic study that suggests itself from the foregoing description.

#### LOCATION AND DESCRIPTION

The typical location of the inferior parathyroid gland is shown in figure 2. The recurrent laryngeal nerve and inferior thyroid artery vary considerably in their location and course, but of necessity they always cross. It is at this point of crossing that the stalk to which I have referred is formed. This slender stalk is usually about 5 mm long and the parathyroid body lies in the inverted V shaped niche formed by the artery and the nerve. Of the forty-four definitely identified inferior parathyroids, thirty-four were found in exactly this location. The remaining ten had stalks of variable length. Some were as long as 4 cm. These may be called ectopic glands and they were found in variable positions, depending, it seemed to us, on the pull exerted by the parathyroid vein which is a tributary to the inferior thyroid vein. The glands, either in the normal habitat or in the ectopic position, were always very close to one of the inferior thyroid veins. Rarely did we find the inferior parathyroid gland in contact with the thyroid gland. It was, then, usually free from the thyroid, posterior to and below it, snugly enveloped in a rug of fat. Figure 3 (inset a) shows the fascia opened, exposing the fatty capsule. Inset b shows the capsule opened, exposing the gland with its stalk entering the hilus. This fatty tissue has a peculiar shape and color that distinguish it from the surrounding adipose tissue, and one comes to recognize it just as one does perineal tissue. In fact, the similarity between embedded adrenal and parathyroid in its fatty capsule constantly impressed itself on us.

While we are not prepared to report on any definite position of the superior parathyroids, certain facts have

Fig. 3—The inferior parathyroid stalk with upper gland in normal habitat. Lower gland ectopic. Stalk continuing into the mediastinum. Inset a fatty capsule of parathyroid. Inset b fatty capsule opened exposing gland with hilus of artery and nerve.

been observed. The stalk is much longer than that of the inferior parathyroid. The arterial supply is usually from the superior thyroid artery, often joined by a branch from the inferior thyroid artery, as illustrated in figure 1. On one occasion it had a branch directly from the external carotid artery, which supplied no other structure. A frequent location of the superior

<sup>7</sup> Churchill, E. D. Parathyroid Tumors Associated with Hyperparathyroidism. *Surg. Gynec. & Obst.* 58: 255-271 (Feb.) 1934.  
<sup>8</sup> Lahey, E. H. Clinical Diagnosis and Operative Technique of Parathyroidectomy. *Surg. Gynec. & Obst.* 60: 1035-1051 (June) 1935.  
<sup>9</sup> Maiman, R. Z. *Chir. f. Zellforsch. u. mikr. Anat.* 22: 20-28 1934.

parathyroid body was about the middle of the thyroid gland, posterior to and near the trachea. In this location the parathyroid is in intimate contact with the thyroid gland. Whenever a parathyroid lies in juxtaposition to the thyroid it is naked, without fatty capsule as contrasted to the typical description given when speaking of the inferior parathyroid, which does not lie in contact with the thyroid gland.

#### SUMMARY AND CONCLUSIONS

A new concept of the anatomy of the parathyroids is based on the constant development of four stalks made up of the parathyroid arteries accompanied by the parathyroid nerves. The nerves, I believe, are described for the first time. Based on our observation of a short inferior parathyroid stalk the normal or typical location for the inferior parathyroid is given. Ectopic glands are accounted for by a long stalk and can often be found when not in the typical location by following this stalk. It is our hope that this contribution will lighten the difficult task of locating and identifying the parathyroid glands.

## MULTIPLE TUMOR SYNDROME IN THE MALE

CARCINOMA OF THE BREAST, PLEOMORPHIC SARCOMA OF THE THIGH AND NEUROFIBROMAS OF THE SKIN. REPORT OF A CASE

GEORGE G. DAVIS, MD

Attending Surgeon Cook County Hospital, Associate Clinical Professor of Surgery, Rush Medical College, University of Chicago

HENRY A. HANELIN, MD

AND

THEODORE C. MOUZAKEOTIS, MD

CHICAGO

We have observed an interesting combination of neoplasms in one individual, each having a different site of origin and location and each presenting an independent clinical problem. It is the combination of a malignant tumor of the thigh and papillary growths of the skin with the relatively infrequent carcinoma of the male breast that makes the case worthy of special notice.

As far as we can ascertain, these tumors have no interrelationship with one another. Yet the fact that the patient has the ability to form new growths from the derivatives of the various germ layers, two of the tumors being malignant and one benign gives a new insight into neoplastic tendencies in man. Heretofore, single or multiple growths from the same germ layer have been noted but the incidence of association of tumors and neoplasms derived from independent embryonal structures has not been extensively dwelt on.

#### REPORT OF CASE

A white man aged 57, a Lithuanian, admitted to our service Jan. 14, 1935, complained of a large swelling on the anterior aspect of the left thigh of six months duration.

The patient stated that he had been entirely well up to six months before at which time he noticed an itching sensation in the upper third of the left thigh. This area which was about the size of a dime (18 mm.) was covered with small red spots which itched so terrifically that he was forced to scratch them in order to obtain relief. A few days later the red spots on the anterior aspect of his thigh disappeared and

were followed by what he termed "black spots," which became raised above the surface of the skin and took on a bluish hue after a few days. This itched only slightly and he was able to relieve himself by gently rubbing the raised area. Within six months this mass grew from the size of a hazelnut to a mass about the size of a small grapefruit. The only particular complaint at the time of examination was that his trouser leg would impinge on the mass and slightly irritate it, so he came in to have it excised.

The general history revealed nothing of special importance except that for a number of years he had worked in a tannery in which he had done a considerable amount of lifting of hides. Being a right-handed man he would brace the bundle with his left leg and throw it over his left shoulder. The force of the lift was transmitted over his left thigh, the left side of the abdomen and the left breast and occasionally over his right shoulder. Lately he had been working as a butcher in the capacity of a meat cutter, wherein he was obliged to handle sections of beef pork and various meats of fairly large size in almost the same manner in which he handled the hides when he worked in the tannery.

On physical examination he did not appear to be acutely ill. He was rather obese. He was not especially perturbed about the growth on his thigh except that it was in his way when he was dressing and walking. The skin was normal except for two papillomas present on his back at the level of the eleventh thoracic vertebra to the right of the middle line.

The pulse was 88, temperature 97 F, respiration rate 20, and blood pressure 150 systolic, 90 diastolic. The head and neck were normal except for a flushed appearance of the face. The chest was of the emphysematous type.

Of especial interest were the breasts, the patient however, had not noticed anything wrong. They were enlarged bilaterally, the left breast (fig. 1) was enlarged, indurated and slightly fixed to the underlying tissue. There was a purplish area in the region of the areola, the nipple was retracted with no secretion, and the whole mass had a slightly puckered appearance. The right breast was enlarged but was not fixed to the underlying tissues. The areola was not indurated and the nipple was protruding. The breast itself covered an area about the size of a quarter (24 mm.) and was very soft to the touch. No secretion was present.

The lungs were essentially normal except for a slightly increased dullness over the chest anteriorly and with some diminution of the breath sounds in the areas of increased dullness.

The heart had a suggestive diastolic blow over the aortic area, associated with a tambour sound at the second aortic. The pulse was full and bounding but the peripheral cardiac signs of aortic regurgitation were absent.

The abdomen and genitalia were essentially normal.

On the left leg (fig. 2) there was a well defined mass about the size of a small grapefruit on the anteromedial aspect of the left thigh at its middle. It was freely movable at its upper and lower poles and slightly adherent to the underlying structures at its base. The overlying skin was a purplish red and in the center of the mass was an area about the size of a five cent piece (21 mm.) which was slightly elevated and was redder than the mass itself. Numerous distended veins were seen coursing through the mass which was soft in consistency and not tender to the touch.

The right thigh and lower leg were essentially normal except that varicosities of both limbs were present.

The impression at the time of the physical examination was that of a sarcoma of the left thigh which was possibly a fibrosarcoma, however a rhabdomyosarcoma was considered. In the differential diagnosis the following conditions had to be ruled out: endothelioma, angioma, varix, hypernephroma and syphilis.

In view of the clinical appearance in the breast the following were considered: carcinoma, sarcoma and gynecomastia secondary to either a tumor of the testicle or a disturbance of the anterior pituitary gland.

Laboratory examinations revealed hemoglobin 80 per cent, red blood cells 4,730,000, white blood cells 7,450, polymorphonuclear leukocytes 48 per cent, eosinophils 1 per cent, lymphocytes 43 per cent, monocytes 8 per cent. Urinalysis was negative, the A. Chalmers-Zondek test was nega-

tive, a complete roentgen study of all the bones, the chest and the abdomen was negative for metastases, and the Wassermann reaction was negative.

The patient submitted to surgery four days after his admission to the hospital, and the tumors of the left thigh and the left breast were excised and submitted to the surgical pathology division for examination by Dr Benjamin Neiman, senior resident pathologist at Cook County Hospital.

Fig 1—Left breast enlarged with induration and retraction of the nipple

The mass from the left breast consisted of an elliptical piece of skin containing the subcutaneous tissues in the center of which was a nipple. The specimen measured 8 by 3 cm. Directly beneath the nipple was a node 2 cm in diameter which

Area 1: Irradiation of left breast and left thigh done at same visit

consisted of multiple cysts up to 5 mm in diameter containing a clear blood-tinged fluid. In the center of this node was a round whitish firm granular area measuring 6 mm.

The whitish nodule seen grossly was composed of a cellular structure with very little stroma (fig 3). The cells were anaplastic showing many mitotic figures and arranged in glandular formations. The cysts seen grossly about the nodule were composed of dilated ducts lined by proliferated epithelium. The lumen was filled with desquamated epithelial and red blood cells.

The mass from the left thigh consisted of a piece of skin and subcutaneous tissue 13 by 11 by 7 cm. The overlying skin was a purple gray. In approximately the center of the

specimen there was a well defined, firm, nonfluctuant node 15 cm in diameter. To the right of this node was a larger and less well discrete swelling 4 cm in diameter, which was slightly fluctuant. On sectioning, the mass was composed of a 10 cm node, this node was made up of confluent smaller nodes, pale purple, gray and mottled with purple red, soft and brainlike in consistency and fusing with the surrounding tissues.

"The tumor consisted of pleomorphic cells and the stroma was scant (fig 4). There were many large multinucleated cells. The nuclei of these were bizarre in shape. The cytoplasm was ample and oxyphilic. Atypical mitotic figures were present and very prominent. Many of the cells had an elongated cytoplasm with fusiform nuclei. The cytoplasm was in intimate relationship with the hyalinized ground substance. In places regressive changes were present, leaving only ghost structures of preexisting tumor cells. A section taken with the overlying skin revealed the tumor to be in the subcutaneous tissues having its origin either in the deep fascia or in the muscle.

'Phosphotungstic acid hematoxylin stain did not reveal cross striations, but the pleomorphism of the histologic picture suggested a myogenic origin.

Microscopic examination of the node removed from the breast showed that it was obviously an adenocarcinoma.

'The node received at a subsequent date which had been removed from the skin of the back, consisted of a pea sized nodule surrounded by a small amount of skin.

"At the junction of the papillary and reticular layer of the cutis there was an irregular, sharply circumscribed and moderately vascular node which consisted of a finely fibrillary ground substance that stained a pale purple gray in contrast to the bright red surrounding collagenous ground substance.

Fig. 2—Pleomorphic sarcoma of the thigh

Encased in the finely fibrillary ground substance there were oval nuclei with a finely granular dense chromatin net. The nuclei were surrounded by a narrow rim of homogeneous cytoplasm that was often not sharply separated from the ground substance. Here and there the nuclei showed a tendency to palisade formation.

'The node removed from the skin gave the histologic picture of a benign neurofibroma. It in no way bore any resemblance to the malignant neoplasm of the thigh. Since the tumor of

the thigh was not neurogenic in origin it could not be interpreted as a malignant transformation of a neurofibroma, which would be very tempting from a clinical standpoint.

The postoperative treatment consisted of high voltage roentgen therapy equivalent to one-half erythema dose weekly. The patient was not always punctual in keeping his appointments however and consequently some weekly doses were missed. The high voltage irradiation was applied over the left side of

Fig 3—Section showing the carcinomatous involvement of the breast (Hematoxylin and eosin  $\times 150$ )

the chest and the left thigh in the regions where the tumors had been excised. The patient has been followed postoperatively for approximately four months and to date has shown a slight increase in weight and no evidences of metastasis at present (table 1).

Kufanoff,<sup>1</sup> in a review of the literature and on the basis of three cases that he had observed, concluded that tumors of the male breast are rare, that cures are more uncommon than in the female, and that benign neoplasms in the male breast are more rare than malignant growths.

Kummer<sup>2</sup> states that cancer in the male breast is most frequent at 60 but is encountered in all ages from 12 to 91, that the right side is more often affected than the left and that bilateral disorders are rare.

Fessler<sup>3</sup> states that "the normal male breast shows gland vesicles from puberty up to the thirtieth year but neither before nor after."

Muellerder<sup>4</sup> approves of prophylactic secondary irradiation at intervals after operation for a prolonged period.

According to Speed,<sup>5</sup> tumors of the male breast furnish 1 per cent of all breast tumors that afflict both sexes. The predisposing causes of male breast tumors are obscure. Trauma due mainly to occupation may have an influence but it cannot be definitely analyzed. However the effect of chronic irritation from occupational pressure or the pressure of clothing may be easier to appreciate.

Samples of a male breast tumor following a single trauma are rare. Manger in seventy-one collected cases in men, found a preceding trauma in twenty-five, Yanamoto, in 257 cases, found a traumatic history in 61.10 per cent, and 10 per cent of all his patients gave a hereditary cancer history.

Wainwright,<sup>6</sup> in an exhaustive study of 408 cases found that the left side was affected more frequently, that the average age was 52.6 years and that symptoms of carcinoma of the breast in men differ from those of carcinoma of the breast in women only in frequency of onset. He concludes that the end results in men are not as good as results in women.

Neal and Simpson<sup>7</sup> studied 152 male breasts among 5,314 breasts encountered in 54,430 specimens submitted for pathologic diagnosis. Non-neoplastic diseases made up 35.52 per cent of the total cases, benign tumors 39.74 per cent, and malignant tumors 23.02 per cent.

Cadore<sup>8</sup> of the University of Pisa in a study of six tumors of the male breast seen between 1911 and 1928 reports the incidence of these tumors as 0.55 per cent of all breast tumors seen during that period.

Gioia and Bianchi<sup>9</sup> agree with Wilms that the histologic pathology depends on whether the primordial cells have arisen before or after the differentiation of the three blastodermic layers.

Gutierrez and Monserrat<sup>10</sup> found the following relation in Argentina: malignant tumor of the male breast 63.1 per cent, benign tumors of the male breast, 36.9 per cent.

Fig 4—Section showing the pleomorphic carcinoma of the thigh. Note the marked pleomorphism (Hematoxylin and eosin  $\times 300$ )

Guez<sup>12</sup> states that cancer of the male breast is very rare in France

In Rosh's<sup>13</sup> studies of a series of 207 breast carcinomas at Bellevue Hospital during the past six years six, or 3 per cent have been in the male. He is convinced of the effectiveness of postoperative irradiation of breast carcinoma in the male as well as in the female

Schreiner<sup>14</sup> reviews 1 664 cases of diseases of the breast seen in the tumor clinic of the New York State Institute for Malignant Diseases, and thirty-one were in the male

Neal,<sup>15</sup> in an exhaustive study, concludes that

- 1 The most frequent lesions of the male breast are non neoplastic processes (46.42 per cent)
- 2 The second most frequent lesions of the male breast are the benign tumors (34.09 per cent)
- 3 The third most frequent lesions of the male breast are the carcinomas (16.23 per cent), tumors of skin origin account for 16 per cent of these, and those of duct or acinus origin account for 84 per cent
- 4 Sarcomas constitute 3.25 per cent of the lesions of the male breast
- 5 Carcinomas of the male breast were responsible for 1.24 per cent of the carcinomas of the breast in both sexes

TABLE 2—Bick's Histologic Classification of Cases

Type	
Hemangioma	11
Sarcoma	20
Fibrosarcoma	13
Neurofibrosarcoma	4
Myosarcoma	1
Myosarcoma	1
Chondrosarcoma	1
Fibroma	1
Neurofibrosarcoma (excluding von Recklinghausen's multiple neurofibromatosis)	2
Carcinoma	1
Total	35

6 Of the sarcomas of the breast in both sexes, 19.61 per cent were found in the male breast

7 Carcinomas are eighty times proportionately more prevalent in the female breast than in the male

8 Sarcomas are sixteen times proportionately more prevalent in the male breast than in the female

9 Carcinomas occur in the male breast only five times more frequently than do sarcomas, whereas in the female breast carcinomas are seen seventy-nine times more often than are sarcomas

10 Of all the lesions of the breast, 3.31 per cent occurred in men

11 The average age of patients at the time of observation for carcinoma was 57.7 years and for sarcoma, 39.7 years

12 The present day standardization of hospitals and laboratories is promoting a better and more extensive diagnosis of tissues and more dependable records from which statistics may be compiled

#### SKELETAL MUSCLE SARCOMA

Bick<sup>16</sup> in a recent article collected a series of thirty-five cases of skeletal muscle sarcoma and says "Tumors involving the skeletal muscles while not of frequent occurrence are by no means rare. Of these, the two most common types are haemangeomata and sarco-

mata." He lists his series of cases according to their histologic classifications (table 2). He writes

Sarcoma may involve the skeletal muscle in several ways. First the tissue of origin may be intramuscular, that is sarcolemma, perimysium, interfascicular connective tissue, the visceral layer of muscle sheath, perineural or perivascular connective-tissue sheaths. Secondly, the tumor may infiltrate the muscle body from a source outside, but in direct contact with it, such as for example, a fibrosarcoma of periosteal or intermuscular fascial origin. This infiltration by direct contact is also the source of intramuscular osteo- and chondrosarcomata. Thirdly, the muscle body may be involved by a metastatic process as occurs when a large secondary fibrosarcoma appears in the muscles and surrounding soft tissues of the thigh following the removal of a supposedly benign fibroma from the plantar surface of the foot.

The statement is repeatedly made that sarcoma occurs most commonly in youth or the young adult. However, fibrosarcoma of the extremities may occur at any age and in fact was found most frequent in the fourth and fifth decades. The ages of the twenty cases listed range from 10 to 60, appearing with maximum frequency between 20 and 40. The age groups for fibrosarcoma and neurofibrosarcoma are similar. This is in marked contrast to a characteristic age of origin for intramuscular hemangiomas. The latter in all probability, invariably a congenital lesion, is usually first noted in early childhood.

Of nine cases of fibrosarcomata in which the duration of tumor was noted, in all but one it was of a year or less. In one case it was two and one-half years. In four cases of neurofibrosarcomata the duration was from seven to twenty-six years. The long duration of a static neurofibrosarcoma followed by a rather brief period of rapid growth often but not always after trauma, is characteristic of tumors of nerve sheath derivation. Likewise, it is not unusual for a fibrosarcoma of the anterior abdominal wall to be discovered only at the time of pregnancy when this tension of the musculature brings a hitherto unnoted sausage shaped tumor into prominence. Although the muscle tumor of relatively short duration suggests a diagnosis of fibrosarcoma, one of longer duration does not necessarily signify benignity. In the presence of a neoplasm which has existed from childhood, hemangioma must be considered, in one of long duration, however, an onset later in life, a neurofibrosarcoma, is a probable diagnosis.

The sites of predilection for intramuscular sarcomas are the thigh, abdominal wall and forearm, sixteen of the twenty cases occurring in these regions with approximately equal frequency. Two of the neurofibrosarcomas occurred in the leg and two in the forearm. Fibrosarcomas occurring in the abdominal wall musculature have long been known under the old clinical name of "desmoid", that is, fibrous tumor. These usually involve the rectus abdominis of either side.

Pain is rarely an early symptom in most instances although a minor ache may have been present at recurring intervals, actual pain either is never experienced or appears only when the tumor is well advanced in size. When present it is apt to be described as "rheumatic." Unlike bone sarcoma, the pain is seldom constant. The presence of pain radiating down a specified nerve distribution is suggestive of but not pathognomonic for a neurogenic tumor or neurofibrosarcoma. Any muscle tumor which in its growth involves a nerve supply will produce radiating pain. Muscle sarcomata may or may not be tender, usually they are not. However occasionally one finds some moderate pain present for a while after a slight trauma.

Ewing,<sup>17</sup> Stout<sup>18</sup> and Cheate and Cutler<sup>19</sup> make no reference to multiple tumors of the leg and skin in association with a tumor of the breast.

#### SUMMARY

A white man, aged 57 clinically and pathologically exhibited a multiple tumor syndrome, each neoplasm being independent of the other and arising from dif-

ferent Anlagen, the tumors were removed surgically and up to the present date our patient has shown no evidence of metastases. He appears to be progressing physically under the course of radiation therapy as outlined.

#### CONCLUSIONS

1. Carcinomas of the male breast are responsible for 124 per cent of the carcinomas of the breast in both sexes.

2. Carcinomas are eighty times more prevalent in the female breast than in the male breast.

3. Surgical excision combined with postoperative irradiation has been found to be the treatment of choice.

4. Skeletal muscle sarcomas may be derived from any of the contiguous and continuous structures anatomically associated with the muscle, treatment here is preferably surgical excision followed by postoperative irradiation.

5. Neurofibromas of the skin are relatively benign neoplasms and in this instance did not show any evidence of malignant change.

### ALOE VERA IN THE TREATMENT OF ROENTGEN ULCERS AND TELANGIECTASIS

CARROLL S. WRIGHT, M.D.

PHILADELPHIA

The use of the fresh whole leaf of aloe vera in the treatment of roentgen dermatitis was suggested by C. E. and Creston Collins.<sup>1</sup> Early in 1935 they reported the case of a woman, aged 31, who had had a severe roentgen dermatitis of the left forehead following a depilating roentgen treatment. Various local treatments were tried without effect and exfoliation and severe itching persisted at the treated site. The patient received a local application of the fresh whole leaf of aloe vera to allay the itching. Within twenty-four hours the sensation of itching and burning subsided and the condition progressively improved within the next five weeks and showed complete regeneration of skin of the forehead and scalp, new hair growth, complete restoration of sensation, and absence of scars.<sup>2</sup>

Radiation sequelae have been classified by Wise and Sulzberger<sup>3</sup> as "(1) pigmentation (2) telangiectasis (3) sclerosis, (4) keratosis, (5) persistent desquamation, (6) wrinkling, (7) atrophy (8) ulceration and (9) cancer." In their hands sequelae characterized by pigmentation, telangiectasis and sclerosis have not responded favorably to treatment with solutions and ointments impregnated with thorium X, radium salts or radon. Ulcerative lesions exhibiting no evidence of malignant degeneration would of course occasionally respond to ointments of these types although Wise and Sulzberger state that Dr. Miesch of the Zurich clinic who has had a wide experience with thorium X, radium and radon preparations in the treatment of x-ray sequelae has abandoned these remedies and employs other palliative as well as surgical methods of treat-

ment. In this country most dermatologists and surgeons have treated radiation ulcers by surgical removal of the affected tissue, closing the defect by sutures, grafts or skin flaps.

Following a personal communication from Dr. Creston Collins in 1934, in which he warned me that results could not be expected in x-ray sequelae of more than two years' duration, I began the use of the fresh aloe vera leaf in the treatment of two cases of x-ray telangiectasia resulting from ill advised attempts at x-ray depilation by local advertising concerns and in one case of radium telangiectasia of ten years' duration. Because of the difficulty of applying the whole leaf directly to the areas in question, I scraped out the intestinal contents of the aloe vera leaf and mixed it with an equal quantity of aquaphor and had the patient massage this into the skin every night.

The aloe vera leaf contains a large quantity of light yellowish green material having about the color and consistency of lemon jello, it is the intestinal material that is used for local application. The directions given by C. E. and Creston Collins are to spread the leaf lengthwise or cut it into thick cross sections, macerate the intestinal material and while it is still fresh to apply liberal quantities to the area to be treated, covering it with a neutral nonporous substance such as waxed paper. A bandage is used to keep it in place.

When a piece of the leaf is applied in this way to an open lesion and removed after several hours the resinous, gelatinous substance of the leaf has apparently disappeared, leaving only the hard outside shell. It would appear that this substance is absorbed by the skin or eroded tissue.

Since October 1934 seven cases of x-ray telangiectasia and the one case of radium telangiectasia have been treated by this method. No improvement was obtained as regards the degree of telangiectasia but the texture of the skin was improved in all cases. One

Fig. 1 (case 2)—Appearance of hands Dec. 23, 1935 (photograph courtesy of Dr. George Prahler).

could not expect that the telangiectasia resulting from excessive x-ray application would be improved by any method that did not include destruction of the enlarged vessels.

My purpose in this paper is to present the remarkable improvement obtained in two cases of x-ray ulceration with the hope of stimulating interest in what promises to be a revolutionary method of treatment for early x-ray damage to the skin and ulceration of the skin resulting from x-rays.

CASE 1—Mrs. C., aged 60, received prolonged x-ray treatment for an eczema of the hands prior to 1920. In 1932 she

1. Collins, C. E. and Collins, Creston. Roentgen Dermatitis Treated with Fresh Whole Leaf of Aloe Vera. *Am. J. Roentgenol.* 33: 596 (March) 1935.  
2. Wise, Fred and Sulzberger, M. B. *Year Book of Dermatology and Syphilology* 1935.

developed fissuring and superficial ulceration of the palmar surface of the right forefinger and thumb. This condition gradually became worse. In June 1935 treatment was started with the aloe vera ointment made as described, with marked improvement in the condition of the hands and complete healing by September 1935. The patient has found it necessary to continue the use of the ointment in order to keep the skin in good condition.

In view of the warning of Dr. Creston Collins that little could be expected in the treatment of x-ray sequelae of more than two years' duration, the results in this case were most encouraging.

The following more striking case illustrates the value of following the method originally suggested by Dr. Collins of employing the plant itself directly to the lesions.

**CASE 2**—Dr. S., aged 43, in 1933 while attempting to remove a needle from a patient's finger under fluoroscopic direction sustained a prolonged exposure to the x-rays, resulting in the production of an acute roentgen dermatitis involving the thumb and the first, second and third fingers of the left hand. This dermatitis appeared approximately two and one-half weeks after exposure. Under application of thymol iodide powder the local inflammation and exudation diminished and the lesion partially healed. In November 1935 the skin of the burned area broke down with the development of superficial ulceration, considerable exudation and crusting. This was the condition

Fig. 2 (case 2)—Appearance of hands Jan. 15, 1936, three weeks after beginning the application of aloe vera.

of the hand when the patient first consulted me at the suggestion of Dr. John H. Stokes, who was familiar with my interest in the treatment of any available roentgen sequelae with aloe vera. The skin surrounding the ulcerating area showed telangiectasia and atrophy. There could be no doubt of the fact that the condition of the fingers and thumb was due to x-ray effects and Dr. Stokes concurred in the diagnosis of x-ray ulceration.

Treatment was immediately started with aloe vera, the leaf being applied according to directions at night, and an ointment of aloe vera (Alvigel as prepared by Dr. Creston Collins) during the day. Applications of the ointment were covered directly with cellophane to promote skin absorption. In three days there was a marked improvement in the appearance of the fingers and in three weeks the skin was virtually healed as is best demonstrated by the accompanying illustrations.

#### SUMMARY

In view of the unfortunate but nevertheless occasional burns that may result from overexposure to roentgen rays, any therapeutic agent that offers a hope of quick healing and relief of discomfort in such sequelae is worthy of further study. From the cases reported it would seem that x-ray ulceration even of several years' duration will respond to the use of aloe

vera. The permanence of results can be determined only by watching cases thus treated over a period of time.

Little can be expected in the treatment of telangiectasia as a result of irradiation beyond a smoothing and softening of the affected skin.

1402 Spruce Street

## RELAXATION OF THE SYMPHYSIS PUBIS IN PREGNANCY

HERBERT THOMS, MD

NEW HAVEN, CONN.

Over two centuries ago Mauriceau,<sup>1</sup> in refuting the opinion that the pubic bones separated in labor, wrote: "Others are of the opinion that these bones thus separated at the time of labour, are thereby degrees a little before disposed by the slimy humours, which flow forth from about the womb, and these mollify the cartilage, which at other times join them firmly." In the light of present-day knowledge this opinion of "others" is of great interest, for relaxation of the symphysis pubis during pregnancy appears to be an established fact.

Relaxation of the pelvic joints during pregnancy has been recognized for many years. As early as 1870 Snelling<sup>2</sup> wrote that "relaxation of the pelvic articulations becomes apparent suddenly after parturition or gradually during pregnancy, permitting a degree of mobility which hinders locomotion and gives rise to the most alarming and distressing sensations." However, it is only within a comparatively short time that accurate observations have been made showing the frequency and degree of separation of the symphysis pubis. In this regard the contributions of Heyman and Lundqvist<sup>3</sup> in 1932 and Abramson, Roberts and Wilson<sup>4</sup> in 1934 are outstanding. The first named authors conclude that the symphysis increases in width in all pregnant women and decreases in width in the postpartum period. In their series of seventy-four pregnant women (forty-eight primiparas, twenty-six multiparas) the average width of the symphysis was within 7 and 8 mm, with a maximum width of 12 mm. The greatest increase was found within the fifth and seventh months of the antepartum period. However, no measurements were made before the fifth month of the antepartum period.

The second named authors studied normal multiparas, normal males, pregnant multiparas and twenty-five consecutive primiparas and concluded that relaxation of the symphysis begins in the first half of pregnancy, progressing but slightly in the last three months, and that retrogression begins immediately following delivery and is usually completed by the end of from three to five months. They also conclude that there is no essential difference between the behavior of the pelvic articulations in primiparas and in multiparas.

From the Department of Obstetrics and Gynecology, Yale University School of Medicine.

This study was made possible through the Research Funds of Yale University School of Medicine.

In the present communication the observations that are reported were derived from a study of 100 primiparous women at different stages of pregnancy, with a brief report of a case in which the pelvic relaxation incident to pregnancy was marked and was associated with severe symptoms. This report of the observations in 100 primiparous women may be said to be essentially that of a consecutive group of individuals since it represents a study of roentgenograms taken for pelvimetric purposes during a six months period.

The method of roentgen pelvimetry employed is the so-called grid method which was developed by my associates and myself in our clinic and is believed to be accurate.<sup>5</sup> In the observations that comprise the present report the narrowest diameter of the symphyseal widening was chosen as the point of mensuration. The grouping of this series into periods of pregnancy noted in months was based on the size of the shadow of the fetal head as shown in the roentgenograms. Those instances in which no fetal head shadow

Fig 1—Appearance Feb 4 1935 at seventh month of fifth pregnancy

#### Observations in One Hundred Primiparous Women

	Number of Cases	Average Symphyseal Spread
Early pregnancy fourth month or less	28	0.36 cm
Fifth month	9	0.42 cm
Sixth month	4	0.52 cm
Seventh month	12	0.49 cm
Eighth month	13	0.55 cm
Ninth month	34	0.58 cm
Symphyseal spread in the first half of pregnancy		
0.2 cm	6 times	
0.3 cm	9 times	
0.4 cm	4 times

0.4 cm	10 times	
0.5 cm	23 times	
0.6 cm	15 times	
0.7 cm	7 times	
0.8 cm	4 times	
0.9 cm	2 times	
1.0 cm	1 time	

was visible I have grouped as belonging to the first half of pregnancy, four months or less. With regard to roentgenograms taken after the fourth month of pregnancy I may say that my experience in interpreting pelvic roentgenograms has led me to assume a reasonable accuracy in determining the duration of pregnancy in months from the size of the shadow of the fetal head.

The observations in 100 primiparous women are summarized in the accompanying table. In the twenty-eight cases of the first half of pregnancy the minimum

spread was 0.2 cm and the maximum 0.6 cm. In the seventy-two cases of the second half of pregnancy the minimum spread was 0.3 cm and the maximum 1 cm.

It may be interesting to note that in the series recorded the pelvis presented the following types according to our classification:<sup>5</sup> round type forty-five times, female type, thirty-seven times, anthropoid type, eighteen times. However no relationship between the amount of symphyseal relaxation and pelvic type was apparent.

There is no doubt that pelvic instability incident to pregnancy changes in the pelvic joints and associated with symptoms of discomfort is far more common than is usually supposed. These symptoms may include pain in the symphyseal region, backache and localized pain in one or both sacro-iliac joints and difficulty in normal locomotion. Such pelvic instability may assume major proportions, as is witnessed in the case here briefly reported.

Mrs. H. R., a white married woman, aged 28, was first seen in the Women's Clinic of New Haven Hospital Sept. 9, 1929, in the fourth month of her second pregnancy. Her first pregnancy had ended at the eighth month with the normal delivery of a 6 pound (2700 Gm) baby. She was not seen again during the second pregnancy until labor had begun, Feb. 20, 1930. At that time she entered the hospital and was delivered spontaneously of a 3670 Gm baby. The puerperium was uneventful.

The patient was next seen Feb. 22, 1931. At that time she was eight months' pregnant and complained of difficulty in walking, which had existed for a period of four months, and stated that she was troubled by her legs 'giving out'. At the time of admission to the hospital she was unable to stand without assistance. Roentgenologic examination showed an abnormal separation of the symphysis pubis with relaxation at the sacro-iliac joints. By the use of a sacro-iliac belt and complete bed rest the patient became asymptomatic. She remained in the hospital and on March 14 was delivered normally of a 3,560 Gm baby after a seven hour labor. Two weeks later examination showed the separation of the symphysis to be much less but still greater than the limits of normal. The patient was discharged from the hospital on the fifteenth day post partum.

She was next seen in the clinic April 6, 1933, at which time she was seven months pregnant. There was considerable tenderness on palpation of the symphysis pubis and a complaint of pain in the left hip whether sitting or walking. Again a sacro-iliac belt was applied which gave considerable relief. She was delivered spontaneously on June 7 of a 3850 Gm baby.

The puerperium was normal except for the complaint of pain in the region of the symphysis and hip joints. During this postpartum period she was placed in a pelvic sling in a Balkan bed. On her discharge from the hospital she resumed the use of a sacro-iliac belt.

On her next admission to the hospital Aug. 18, 1934, she stated that her last period had occurred two months previously. Examination showed that the patient was pregnant. After the sixth month of this pregnancy she complained of marked pain in both hips which was aggravated by motion and weight bearing. Feb. 1, 1935, the pain was so severe that she was

Fig 2—Appearance Nov. 6 1935 at eighth month post partum

<sup>5</sup> A description of the technic may be found in Thoms, Herbert: The Obstetric Pelvis. Baltimore: Williams & Wilkins Company, 1935, p. 22.

unable to sit or lie with any comfort except at brief intervals. She was admitted to the hospital and placed in a pelvic sling which as before gave relief (fig 1).

Because of the unusual past history, delivery by cesarean section with sterilization was advised, to which the patient and her husband consented. Accordingly, on March 23 cesarean section followed by supravaginal hysterectomy was performed. Since the operation the patient has been more comfortable and the separation of the symphysis as shown by roentgenologic examination has decreased to about 0.5 cm. Nevertheless, at the present time she complains of marked tenderness in both gluteal regions which is worse at night, and the orthopedic consultant feels that eventually she will need an operation to correct the abnormal pelvic mobility (fig 2). In this instance trauma did not seem to be an etiologic factor. There was no history to support this as a cause and the labors were easy and spontaneous.

As early as 1812 LeGallois<sup>6</sup> pointed out that in the female guinea-pig the pelvis is only about half the size of the fetal head and that before parturition takes place the ligaments joining the pubis become thick, soft and malleable so that the pubes gradually separate. Knox<sup>7</sup> in 1839 observed a similar process in the pregnant seal, and Bailou<sup>8</sup> in 1854 described somewhat similar changes in the pregnant cow, particularly in the sacro-iliac joints. In 1932 Hisaw<sup>9</sup> was able to isolate from the blood of guinea-pigs, dogs, cats, sows, maies and rabbits during pregnancy a substance which, when injected into the virgin guinea-pig at estrus, would produce in a few hours the same relaxation of the pelvic ligaments noted in the same animal before parturition. More recently Gardner<sup>10</sup> has reported similar results in male mice following the injection of "folliculin benzoate".

From the investigations of the authors quoted it seems probable that the mechanism of pelvic relaxation during pregnancy in the human species is one of hormonal control.

#### CONCLUSIONS

1 Pelvic joint relaxation especially that of the symphysis pubis, is manifested in normal pregnancy.

2 From the examination of a series of 100 primiparous women at different stages of pregnancy it would appear that this relaxation is a progressive phenomenon.

3 The degree of pelvic relaxation accompanying pregnancy may assume serious proportions, as noted in the case presented.

4 Recognition of symptoms suggesting pelvic relaxation should demand thorough roentgenologic investigation in order that early treatment may be instituted.

5 Valuable information may be gained from the routine roentgen pelvimetry of all primiparous women.

**Vitamin Insurance in Winter**—Vitamin D, like vitamin A, can be stored in the body to an important extent and the demands of pregnancy and lactation can be met in part by drawing upon the bodily store of the mother. As insurance, however, it is well to provide liberal intakes of vitamin D to pregnant and nursing mothers and to breast-fed as well as bottle-fed infants. Fish liver oils and some of their concentrates have the advantage of furnishing both vitamins A and D and are probably desirable supplements to the diets of all children during the winter months.—Sherman, H. C. *Food and Health*. New York: Macmillan Company, 1934.

## THE INCREASING IMPORTANCE OF PNEUMOTHORAX THERAPY IN PULMONARY TUBERCULOSIS

J. W. CUTLER, MD

Physician in Charge of Pneumothorax Clinic, Henry Phipps Institute, University of Pennsylvania

PHILADELPHIA

Collapse therapy is not new, either in theory or in application, but after a long period of development has become increasingly popular in this country within the last decade. Artificial pneumothorax was suggested as a form of treatment for pulmonary tuberculosis by James Carson in England in 1821 as "simple, safe and complete." It was discussed by Forlanini in 1882, the very year in which Koch announced the discovery of the tubercle bacillus, and was applied by him clinically in 1888. It was practiced in this country as early as 1898 by John B. Murphy. A considerable number of papers on the subject have appeared regularly since but until recently collapse therapy has made relatively little progress in this country. Pneumothorax has been regarded as a sanatorium procedure, the recognized indications were narrow and the number of cases treated comparatively few. On the other hand, with the rapidly increasing application of all forms of collapse therapy, therapeutic pneumothorax is now probably overdone. Nevertheless those who have long been acquainted with the hardships and suffering caused by tuberculosis and its toll in human lives and are able to compare the results of the older and newer forms of management feel assured that the gain has been greater than the loss. What is needed is to train the new generation of tuberculosis specialists so that in seeking dramatic results they will not lose sight of fundamental and established principles. The operator should have a thorough grasp of the disease and of the physiologic processes of pneumothorax, otherwise there are potentialities for harm in the present enthusiasm.

What are the more important considerations that have contributed to this change in the treatment and management of pulmonary tuberculosis? They are apparent when one considers critically the obstacles that have to be overcome to obtain a lasting cure in tuberculosis of the lungs.

#### THE CONTROL OF THE TUBERCULOUS TOXEMIA

The most urgent problem in arresting clinical tuberculosis is control of the toxemia that always accompanies to a greater or less degree the active phases of the disease. It is apparent when one considers the physiopathologic aspects of pulmonary tuberculosis that there can be no beginning of cure until the toxemia is checked. The familiar symptoms of tuberculosis, such as fever, night sweats, loss of appetite, anorexia and rapid pulse are the constitutional manifestations of the toxemia caused by the pathologic process in the lung tissue. It is the resulting toxemia that makes the patient feel ill.

Whether the toxemia is acute or chronic, it always disturbs health and in turn favors a spread of the tuberculosis in the lungs. This spread results in more toxemia, and a vicious cycle is established. If the toxemia is of low grade the end may be delayed for years. The patient may even enjoy relatively good

From the Henry Phipps Institute, University of Pennsylvania School of Medicine.

health and be a useful and productive citizen with long periods of remission. These are the so-called "good chronics." On the other hand the toxemia may be acute and apparently out of all proportion to the extent of the disease in the lungs, and the patient may die in a few weeks.

To effect a cure one must first of all break through the vicious cycle and reverse the trend. With the toxemia eliminated or checked the fever disappears, the appetite improves and there is gain in weight and strength. This in turn gives an opportunity for the natural healing forces of the human body to come into play and resolution and scarring of the pulmonary lesion usually follows in due course, until the patient becomes anatomically cured.

Unfortunately there is no specific in the treatment of pulmonary tuberculosis to control the toxemia, no drug, similar to quinine in malaria, no antitoxin as in diphtheria, indirect methods must be depended on.

In the past, reliance has been placed on bed rest and less soundly, on climate and altitude, on fresh air and tonics, on milk and eggs. If one analyzes the reports from institutions in various parts of the country, some noted for their beneficial climate others not, the results are essentially the same, and except for incipient cases they are disappointing. There was little that could be accomplished for the larger number of patients, and many institutions until recently denied admission to all but "early" cases. A diagnosis of far advanced tuberculosis often meant death or a life of invalidism.

It slowly became apparent that the reason for failure in many cases was that even rest in bed was not sufficient rest for a tuberculous lung. The natural process of breathing was too much exertion, and although absorption of toxic products into the circulation might be diminished, it was not eliminated and the patient would continue to get worse and finally die. What was needed was intensive local rest for an indefinite time. This can be accomplished only by collapse therapy. When pneumothorax treatment is instituted, the diseased area of the lung is collapsed and squeezed together like a sponge. The source of the toxemia is shut off and further absorption of toxic products eliminated. For this reason the immediate results of artificial pneumothorax are often dramatic. The fever drops, the night sweats disappear, the appetite returns, the patient gains in weight and strength and almost over night the clinical picture is changed from one of despair to one of cheerfulness and hope. This is due to no other factor than the elimination of the toxemia. The lung itself is still diseased. The cavity and infiltration are still there as they were before collapse was instituted. If reexpansion is permitted all clinical symptoms of active tuberculosis return.

The first principle therefore, in the treatment of clinical tuberculosis is the immediate control of the toxemia at its source. The most rapidly effective way to accomplish this is to collapse the lung if possible by establishing an artificial pneumothorax. When the collapse is efficient it accomplishes more in a few weeks than could be brought about in months or even years by older methods. Pneumothorax materially improves the immediate prognosis of pulmonary tuberculosis.

The following summarized case report illustrates the dramatic effect of pneumothorax on the tuberculous toxemia.

CASE 1—S. S., a white man, aged 23 came under observation Dec 19 1929 with advanced tuberculosis involving the right upper lobe and complicated by hemoptysis. He had been

acutely ill for two weeks previously. His evening temperature ranged between 102 and 103 F and he was coughing up large mouthfuls of blood at frequent intervals. At times there was a fresh hemoptysis of several ounces. Under rest in bed and medication his condition did not improve and the outlook appeared grave. Pneumothorax was instituted December 21 and a partial collapse of the right lung obtained. The bleeding stopped almost at once and after the second inflation three days later disappeared entirely. The fever began to disappear and by the end of the nineteenth day the temperature had returned practically to normal. The clinical appearance of the patient was strikingly improved and at the end of six weeks he was permitted out of bed. His recovery has been uneventful. It has been nearly six years since he first became ill. He has been working and self supporting for the past five years without the loss of a single day because of his tuberculosis. The lung is practically healed and it would probably be safe to permit reexpansion, but the patient feels safer with the lung collapsed and has asked that the treatment be continued. The dramatic response of his tuberculosis to pneumothorax is indicated in figure 1.

#### IMPORTANCE OF TIME IN THE CURE OF TUBERCULOSIS

The second consideration in the treatment of tuberculosis is the factor of time. Cure is usually a matter of years. Even minimal tuberculosis requires a year or more for a lasting cure. The great mistake made in the past in treating tuberculosis was the assumption

Fig. 1 (case 1)—Daily temperature curve in a case of acute tuberculosis treated by artificial pneumothorax (refills indicated by arrows).

that clinical well being was synonymous with cure. It has been shown that the patient may feel well, gain in weight and have a normal temperature while the disease in the lungs progresses. This is a common experience with the record clearly written in serial x-ray studies. For this reason relapses have been common following apparent cure of the disease after a prolonged sojourn in a sanatorium and many sanatoriums, regarding tuberculosis as a relapsing disease with a gloomy prognosis, have restricted admission to early cases.

The difficulty has been that the principle of rest for the diseased lung has not been applied long enough and in some cases could not be applied intensively enough, however faithfully the patient might "take the cure." Most physicians have centered their attention on the outward manifestations of clinical tuberculosis and have overlooked the evidence showing that anatomic improvement lags far behind clinical improvement. Moreover, many tuberculosis patients could not or would not remain in sanatoriums or stay in bed for the time required to obtain a lasting cure, particularly after they began to feel well.

Collapse therapy attacks this evil at its source. When therapeutic pneumothorax is instituted the lung is splinted and kept at rest for as long a period as the physician may desire, two years, five years or for the rest of the patient's life if need be. With the toxemia

controlled and the patient feeling well and able to work, all that is needed to keep him in good health is to maintain the pneumothorax sufficiently long to permit complete healing of the tuberculous lung. Serial x-ray studies are evidence of the remarkable healing power of nature, large cavities and massive infiltrations may in time disappear and leave little trace.

Regardless of how impressive the immediate results of pneumothorax may be, the physician must remember that a lasting cure always takes time. Experience has shown that in the majority of cases from three to five years is necessary, and in some instances longer. There can be no fixed rule as to how long pneumothorax should be maintained. If a general rule may be ventured, it would be to continue pneumothorax for at least a year after the x-ray evidence indicates complete healing. In the majority of cases this means from three to five years, depending on the extent and severity of the disease at the time treatment was instituted. Early cases naturally require less time, perhaps two years. No patient should be started on pneumothorax therapy with the idea that within six months or a year he will be cured and that the treatment can be safely stopped at the end of that time. Figures 2 and 3 show

Fig. 2—Chest of a white woman aged 22, June 17, 1932. Bilateral pneumothorax shortly before the pneumothorax on the right was discontinued after three years of uninterrupted successful collapse. Except for a few fibrous strands in the right upper lobe the lung was apparently free from disease. The sputum was persistently negative for tubercle bacilli and the patient was clinically well.

recurrence of advanced disease after pneumothorax treatment of three years' duration was discontinued shortly after x-ray evidence of apparent cure. The lengthy period of treatment is no particular hardship. It is not even an important inconvenience and all in all is a very small price to pay for good health. Once the toxemia is eliminated, usually in the first few months, the patient can work and live a normal, useful

life within reasonable limits. Women may bear children and young people may continue with their studies. There is no reason why in the light of modern experience a tuberculous patient, properly treated, need have his life's ambition thwarted and be forced to live the life of semi-invalidism. The following case illustrates the possibilities of modern collapse therapy.

CASE 2—S. T., a white woman, aged 27, seen in consultation April 19, 1932, had far advanced bilateral tuberculosis with cavity formation and positive sputum (fig. 4). She had not been well for ten months previously following the birth of a daughter in 1931 and complained of a hacking cough, unexplained weakness and loss of weight and some expectoration. Six weeks after delivery she had a small hemorrhage of about 2 ounces (60 cc). During April she had frequent night sweats. Her evening temperature averaged close to 100 F. Pneumothorax therapy was instituted at home on the right side on April 26, one week after the diagnosis was made and a satisfactory collapse was established. June 22, phrenic evulsion was performed on the left side. October 18 the patient had a tonsillectomy under local anesthesia for frequent sore throats. Her health has steadily improved. Her sputum became persistently negative for tubercle bacilli and by December 1932 she

assumed full household responsibilities. In 1933 she became pregnant (fig. 5) and on Jan. 19, 1934, she gave birth to a healthy baby girl without any deleterious effect to her health. She is still receiving pneumothorax treatment (December 1934) for the right lung, and the left diaphragm is still elevated (fig. 6). Her lungs, while still diseased, have improved considerably and she is as active as any normal woman.

The unique ability of the induced pneumothorax to keep a diseased lung at rest indefinitely accounts for the larger percentage of cures among such patients as compared with those treated without pneumothorax. Rist has pointed out that the difference may be as great as 52 per cent as compared to 85 per cent. In other words, by his calculation a patient with moderately advanced tuberculosis treated with pneumothorax has a chance for ultimate recovery six times as great as the patient treated without pneumothorax.

#### THE ECONOMIC AND SOCIAL PROBLEMS IN TUBERCULOSIS

Another important consideration in the treatment of tuberculosis is the proper management of the underlying social and economic problems that are so intimately associated with this disease.

The great majority of patients are persons who depend for their bread on their daily earnings. If it is made impossible for such an individual to keep his job, or if too heavy a financial burden is put on him when he attempts to provide medical care for a member of his family, it is difficult or impossible for him to solve his particular economic problem. Many, given no alternative, after a heroic effort, which quickly dissipates their meager resources, are sooner or later forced to accept charity and free medical care. Social service studies have repeatedly shown that, of all diseases responsible for patients seeking relief in normal times, tuberculosis occupies first place. This has been a necessary corollary when treatment necessitated migration to a sanatorium located at a distance and a sojourn there for months and years. Only a relatively small number can afford such luxury, and, even among these, financial sacrifices have been common. Pneumothorax therapy has in many instances eliminated the necessity for sanatorium care and other expensive hospitalization. It can be safely instituted at home or in a local hospital. The majority of patients are more comfortable at home, where they usually have better quarters and better food. If the collapse is effective they gain in weight and strength rapidly in their accustomed surroundings and within a short time are able to take up their daily work again without prejudice to their health.

These facts are so well established today that more and more tuberculosis specialists, particularly in the larger cities, treat their patients at home with collapse therapy instead of sending them away. This change in management incidentally helps to reduce the cost of medical care and to maintain the private relationship between patient and physician. It has made it possible for a considerable number of patients who otherwise would be forced to seek free medical care in the city or state institution to receive skilled private medical care in their homes.

If the toxemia is not severe and the disease not too far advanced, if it is confined to one lung and if a satisfactory collapse can be established—conditions found in about 50 per cent of the tuberculous—1 patient may return to work in from one to three months after pneumothorax treatment has been in-

uted More is accomplished within this short time and at a relatively insignificant cost than would have been thought possible under any other form of treatment heretofore

The following is an example of the economic value of artificial pneumothorax in a young adult with advanced, active tuberculosis of one lung

CASE 3—E F, a white woman, aged 25, was diagnosed at the Henry Phipps Institute, April 20 1930, as suffering from an acute tuberculous consolidation of the right upper lobe. The temperature was 102 F and the pulse 100. Rales were easily detected in the consolidated area and the blood sedimentation rate was rapid, with an index of 24 mm. The sputum was positive for tubercle bacilli. The patient refused hospitalization and sanatorium care. Artificial pneumothorax was started at home on May 2 and a good collapse was obtained. Three weeks later, against advice, she resumed her position as a clerk in a department store, free from all symptoms and apparently enjoying good health. Her sputum became free from tubercle bacilli. Five years has now elapsed. The patient has not lost a day from work because of illness. She looks well, is free from all symptoms and the consolidated area has entirely cleared up. A recent roentgen study disclosed an apparently healthy lung with a number of fibrous strands in the previously diseased area.

This has been accomplished under artificial pneumothorax with the patient at work and self supporting. The only inconvenience to the patient was the refills. Artificial pneumothorax is the only treatment that can meet the urgent financial needs of such patients, enabling them to work without prejudice to their own physical welfare and without exposing either their families or their fellow workers to contagion.

Even in the poor the disease can be managed efficiently in their home environment by means of collapse therapy. The ambulatory pneumothorax clinic at the Henry Phipps Institute, organized in 1931 in the heart of the slum district of Philadelphia, where poverty and bad hygienic conditions are common, treats about fifty patients a morning with results that compare favorably with similar groups of patients treated in well regulated sanatoriums. The field pneumothorax clinic of the Chicago Municipal Tuberculosis Sanitarium and similar clinics in other metropolitan centers report similar results. The economic and health value of such a plan to the community is obvious.

Sometimes there are other factors in addition to the economic that contribute to the hardships and tragedies of tuberculosis. Case 4 illustrates this point.

CASE 4—A dentist was stricken with active tuberculosis of the lungs and positive sputum just as he was becoming established in his profession. Without ambulatory pneumothorax, residence in a sanatorium for at least six months or a year would have been necessary with probable loss of his practice and of his many valuable contacts established after hard work and patient effort.

He was seen in consultation on June 12 1933. At that time he had advanced tuberculosis of the right upper lobe with a cavity 3 by 4 cm., cough and positive sputum and an evening temperature of 99.4 F. He was greatly disturbed about his social problems, above all else he did not want to close his office and go away. In spite of the advanced character of his disease it was confined to one lung and his general condition was good. He was well nourished and toxemia was not pronounced. It was an easy matter for him to announce that he was going away for a two weeks vacation. During this time he remained at home and pneumothorax was instituted. Fortunately the collapse was satisfactory, the cavity closed almost immediately, the sputum became negative and the fever disappeared. At the end of two weeks he was in his office again practicing dentistry. He was instructed to rearrange his hours and to restrict his work within certain easy limits.

Every spare moment he rested on a couch in his office. Little by little his working hours were increased. In the two and a half years since he was first placed under treatment pneumothorax has been maintained and at present he receives a refill every three weeks. His lung is practically healed and there is no trace of the cavity. His life is normal in every respect. What other form of treatment could have accomplished as much in so short a time?

#### THERAPEUTIC PNEUMOTHORAX AS A PUBLIC HEALTH MEASURE

The public health aspect of tuberculosis must never be overlooked. Pulmonary tuberculosis is a contagious disease and spreads from individual to individual through continued intimate contact. In a sense the physician who undertakes the treatment of a tuberculous patient becomes the public health officer responsible for the welfare of the entire family and indirectly of the community. The physician must therefore always be on the lookout for sputum containing tubercle bacilli and his treatment and management of the case must take into account this vital factor. Education of the patient and his family in the proper disposal of the sputum is of course, a help but a more effective method is to render positive sputum negative.

When the diseased lung is satisfactorily collapsed tubercle bacilli almost invariably disappear from the sputum. This occurs so regularly after an effective collapse has been established that, if the sputum remains positive, it is evidence that the diseased area is not as effectively collapsed as was believed or that there is active disease in the contralateral lung. As soon as the sputum is freed from tubercle bacilli

by collapse the danger to others in treating tuberculosis at home is eliminated.

If by such a relatively simple procedure as pneumothorax a goodly number of tuberculous patients can be rendered harmless to those about them through the disappearance of tubercle bacilli from the sputum there is in this procedure one of the most powerful weapons in the control of tuberculosis. Artificial pneumothorax must therefore be regarded as a public health measure of the first magnitude.

#### IMPROVEMENT IN PNEUMOTHORAX TECHNIC

Another factor that has contributed to the popularity of pneumothorax is a better understanding of its method of operation. There has been considerable improvement in technic and the routine use of the fluoroscope and roentgenograph has placed the treatment on a sound scientific basis. When Forlanini practiced pneumothorax therapy it was believed that the entire lung, both the diseased and the healthy area,

Fig. 3—Aug. 2 1934 twenty six months after the pneumothorax on the right was discontinued. There was recurrence of widespread tuberculosis in the right lung with several small cavities in the upper lobe. A phrenic crushing and scalenotomy was performed but has failed to close the cavity. The sputum is positive for tubercle bacilli and the patient is confined to bed for the most part (December 1934). During this period the disease in the left lung has steadily improved under pneumothorax treatment to the point of almost complete clearing.

had to be collapsed, and the lung was shrunken to a sausage shaped mass lying close to the heart. Under such conditions treatment was necessarily confined to strictly unilateral cases. But it has long since been established that all that is necessary is collapse of the diseased part, while the healthy tissue is permitted to function. This is the principle of selective collapse. With this type of therapy, little or no strain is placed on the contralateral lung, and very often, in fact, when disease is present in the "good side," this also improves

Fig. 4 (case 2)—April 19 1932. Far advanced bilateral active tuberculosis with a cavity in the right upper and one near the left hilus. Duration of symptoms ten months following childbirth.

with the improvement of the treated lung. Furthermore, selective collapse makes possible bilateral pneumothorax or the simultaneous collapse of parts of the two lungs. This improvement in technique has materially increased the usefulness of artificial pneumothorax and widened its indications, so that it can be applied to an increasing number of patients. There are many institutions

today in which pneumothorax is applied to 75 per cent or more of the tuberculous patients, in marked contrast to the usual 5 to 10 per cent of a decade ago.

#### INDICATIONS AND CONTRAINDICATIONS FOR PNEUMOTHORAX TREATMENT

It follows that the trend today is to institute pneumothorax or some other form of collapse therapy whenever possible and to do it as soon after the diagnosis is established as is practicable. In the average case there is nothing to be gained by waiting a few months to see how the patient will respond to bed rest alone. The exceptions to this rule are taken up in later paragraphs under contraindications.

Such complicating conditions as diabetes or pregnancy call for immediate application of pneumothorax therapy. The same is true for tuberculosis of the larynx, which at times will improve with surprising rapidity with collapse of the diseased lung. In fact, the many conditions that formerly were regarded as contraindications are today added indications.

**Latent or Asymptomatic Tuberculosis**—Is pneumothorax indicated in latent tuberculosis? Opie and McPhedran have defined latent tuberculosis as tuberculosis of the lungs without physical signs or symptoms but clearly demonstrable in the x-ray film. This definition does not indicate that the disease is necessarily harmless. Not infrequently the tuberculosis is active and advanced, as shown by serial x-ray films and also in blood sedimentation studies, and if allowed to go unchecked will in time result in clinically manifest tuberculosis with positive sputum and cavity formation. On the other hand there are a considerable number of patients with latent tuberculosis in whom the disease will never become of clinical importance.

Obviously, common sense should be the guiding rule as to whether pneumothorax is to be instituted in latent tuberculosis. If the disease is inactive it may be a

healed tuberculosis, and for all practical purposes except for periodic examination, no supervision is indicated. The diagnosis is purely an anatomic one. On the other hand, if the disease appears active and advanced the patient should be treated with as much seriousness as if he already had manifest clinical tuberculosis. These patients are potentially curable with relatively little effort, but there is no need for the immediate institution of pneumothorax therapy. The situation can be explained to the patient and his family and the patient ordered to bed for about three months. If he improves, this period of rest can be continued and the patient treated along the established hygienic dietetic-rest regimen. On the other hand, if the disease shows a tendency to progress or if the patient objects to prolonged bed rest, pneumothorax intervention is definitely indicated. In the Negro race, because of the great tendency of the disease to progress rapidly and with little warning, the latent period—the period before symptoms develop and before tubercle bacilli make their appearance in the sputum—is the most favorable time for pneumothorax intervention.

**Closed Tuberculosis**—What has been said for latent tuberculosis applies equally well for clinically closed tuberculosis, with the clinical signs and symptoms of tuberculosis but no tubercle bacilli in the sputum. If the disease is not advanced, bed rest alone should be tried first. But if after a trial of some three months the roentgenogram, regardless of apparent clinical improvement, shows a tendency for the disease to progress, pneumothorax treatment may be instituted without further delay. If the sputum should at any time become positive or if the disease is advanced when the diagnosis is first made, pneumothorax should be instituted at once for public health reasons.

**Far Advanced Tuberculosis**—It has already been emphasized that pneumothorax is not a specific. It produces its results by resting the lung, eliminating the toxemia, perhaps by shutting off the oxygen supply to the tubercle bacilli and by favoring fibrosis. It helps to set in motion the natural forces of the body for recovery. If, however, the patient has not enough resistance to tuberculosis, or if too much lung has been destroyed, recovery cannot be expected. There must come a time, therefore, when the application of pneumothorax is a wasted effort. Just when this is true may be difficult to decide in individual instances. If the disease is advanced in the two lungs to the extent that 50 per cent or more of the total lung tissue on both sides is destroyed, pneumothorax will produce little or no result and may be said to be contraindicated. If pneumothorax is applied to some of these patients it may even shorten life by interfering with the fine

Fig. 5 (case 2)—Dec 12 1933 twenty months later. Pneumothorax on the right side and phrenic evulsion on the left. There has been marked clearing in both lungs with the cavities no longer visible. Sputum persistently negative for tubercle bacilli. Patient pregnant and near term. Note the very high position of the left diaphragm and the distended colon below. No noticeable dyspnea.

balance that the patient has somehow managed to build up, enabling him to enjoy a certain degree of well being

Pneumothorax should not be instituted in obviously dying patients with hectic fever and cyanosis, in whom the disease is widely scattered in both lungs. Likewise pneumothorax should not be instituted in those who have some other disease which in itself will kill the patient or keep him a confined invalid, such as cancer or progressive deforming arthritis.

**Hypertension and Heart Disease**—Patients with definite hypertension—180 mm or more—do not as a rule do well under pneumothorax therapy. They do not tolerate interference with the intrapleural pressure, and marked shortness of breath with a broken cardiac compensation may result. These patients are best treated by the usual dietetic-hygienic-rest regimen. The same holds true of patients who give a history of cardiac decompensation.

On the other hand, the presence of an organic valvular lesion with good compensation is not a contraindication. Excellent results can be obtained in the presence of definite mitral stenosis and regurgitation.

**Age**—This is at times considered a contraindication. However, pneumothorax has been given to infants 5 months old and to adults in their late sixties and older. As a general rule, however, patients beyond 50 are easily upset when the intrapleural pressure is changed by pneumothorax therapy. They become noticeably short of breath even when small quantities of air are introduced. This shortness of breath is presumably due to the arteriosclerotic changes in the larger vessels and to a weakened cardiac musculature, which cannot accommodate themselves readily to the increased intrapleural pressure. If, however, the disease is progressive and the prospects for a cure are good, one should not hesitate to employ pneumothorax therapy and adjust the technic accordingly.

**Asthma**—This is often considered a contraindication. If the prospects for a cure are good however, the asthmatic patient who has pulmonary tuberculosis should have pneumothorax treatment. Such patients often do well in spite of repeated attacks of asthma. In rare instances the asthma is due to allergy caused by the tuberculosis, and the patient may be cured of his asthma at the same time that the tuberculosis is cured.

**Extensive Adhesions**—Pneumothorax should not be forced in those cases in which no free pleural space exists, nor should it be continued when it becomes evident that a cavity cannot be closed because of extensive, inoperable adhesions. If one persists in pneumothorax therapy under such circumstances air embolism and sudden death may result or tuberculous empyema and other serious complications may set in. These patients are not suitable for pneumothorax but may be helped by phrenicectomy or thoracoplasty. The important thing is for the operator not to lose valuable time with an ineffectual pneumothorax.

#### COMPLICATIONS

In a discussion of pneumothorax therapy it is important to indicate its dangers and complications. Like any other form of treatment pneumothorax has its dangers. These should always be kept in mind but they can be exaggerated. One should always balance the possible complications of pneumothorax therapy against the alternative of not instituting collapse treatment, for passive treatment has its complications also.

It is also important to keep in mind that the earlier in the course of the disease pneumothorax is instituted the less will be the likelihood of serious complications.

**Air Embolism**—The most important single complication is air embolism. It is the cause of practically all sudden deaths following pneumothorax treatment. It occurs in some degree about once in 1,500 pneumothorax treatments and in less than 0.5 per cent of all treated cases. It is not fatal however, in this number as in the majority of instances the patient recovers. When it does occur it is almost invariably due to faulty technic, of which the operator may not have been aware at the time. A careful analysis of such cases will usually convince one that there has been an attempt to inflate the pleural cavity when there were definite warnings that the needle was not in the proper place or that no free pleural space was present. The technic of pneumothorax in the average case is so easy that the operator, unless he has seen a sudden death from artificial pneumothorax, may look on the treatment as simplicity itself, devoid of all danger, and in his ignorance take chances in difficult situations. The danger of air embolism is naturally greatest when pneumothorax treatment is first instituted, and there should be an unaltered rule that no one but a thoroughly experienced operator should give the initial treatment. This complication, while always potentially present, can be eliminated almost entirely by close attention to all details of technic, by routine fluoroscopic studies before each refill and by a keen awareness of possible danger on the part of the operator.

Fig. 6 (case 2)—Nov. 3, 1935 twenty-one months after giving birth to a healthy baby girl. There has been uninterrupted healing in both lungs. The patient is symptomatically well and able to work (December 1935). Note the lower position of the diaphragm following childbirth. The left side is still elevated as a result of the phrenic nerve evulsion.

#### Pleural Shock

Dizziness or discomfort after a pneumothorax refill is not uncommon, but serious consequences from pleural shock are extremely rare. When such symptoms occur and end in death they are almost invariably due to air embolism and not to pleural shock.

**Pleural Effusions**—Pleural effusions during pneumothorax therapy are very common. They fall into two distinct groups.

(a) **Pleural Transudates**—Pleural transudates occur sooner or later in 90 per cent or more of patients receiving pneumothorax treatment. They seldom rise above the eighth posterior rib and in time disappear. They are of no clinical importance. They require no treatment and should not be considered a complication. In fact the small effusion often acts in a beneficial way by decreasing the permeability of the pleura to air and making it possible to lengthen the intervals between refills. It is the result of the natural reaction of the pleura to the presence of a foreign substance, the introduced air.

(b) *Tuberculous Pleurisy* Tuberculous pleurisy, acute or chronic, is relatively common in tuberculosis and may occur at any time in the course of the disease, regardless of the type of treatment instituted. Occasionally it appears that an acute pleurisy is precipitated by pneumothorax treatment, but acute pleurisy is not more common during pneumothorax treatment than without it. It occurs in about 5 to 10 per cent of treated cases. About 50 per cent of these acute pleurisies disappear spontaneously or after aspiration and air replacement and do not interfere with the ultimate cure of the patient.

(c) *Tuberculous Empyema* Approximately 50 per cent of all tuberculous pleurisies persist in spite of repeated aspiration and in time become purulent. Some of these will respond to continued aspiration and disinfectant oleothorax and in time will clear up completely. In others the fluid persists but accumulates very slowly and does not interfere with the general health of the patient. If the lung is effectively collapsed, the sputum negative and the patient doing well clinically, the pneumothorax should be continued until a cure has resulted. The small empyema will disappear when the lung is ultimately reexpanded. On the other hand, if the collapse is ineffective and there is still an open cavity, thoracoplasty is the best solution. In all events tuberculous empyema properly treated is not the serious complication that it was once believed to be. Furthermore, it occurs chiefly in far advanced cases with large cavities and can be avoided by instituting pneumothorax earlier in the course of the disease.

*Spontaneous Pneumothorax*—This may be due to the induced pneumothorax, as when an adhesion gives way at its visceral attachment, especially when the cavity is situated superficially, or it may occur in the natural sequence of events, because of the progressive character of the tuberculosis in spite of treatment. At least 5 per cent of all tuberculous deaths in patients who never had pneumothorax treatment are from spontaneous pneumothorax. This incidence does not appear to be greater under pneumothorax treatment, and, when it does take place, the chances are that it would have occurred with or without collapse therapy in the course of progressive disease. The practice of forcibly stretching adhesions to close cavities accounts for some spontaneous ruptures and should be abandoned. The possibility of these spontaneous pneumothoraces can be materially reduced by early intrapleural pneumolysis.

*Disease in the Contralateral Lung*—Spread of the disease in the opposite lung does occur under pneumothorax treatment, but much less frequently than under passive treatment. In the majority of instances the reverse is true—the opposite lung improves following improvement in the treated lung. If necessary, however the contralateral lung can be treated by the bilateral induction of pneumothorax or by phrenicectomy. Some of the extensions of the tuberculosis in the other lung are due to faulty technic in establishing a collapse on the badly diseased side and can be prevented.

*Other Complications*—The other complications such as displacement of the mediastinum, subcutaneous emphysema and pneumothorax fever although inconvenient are of little importance. They do not interfere with the treatment nor do they endanger the welfare of the patient.

#### COMPLICATIONS OF PASSIVE TREATMENT

Treatment without pneumothorax is also not without danger and against the complications of collapse therapy just described must be placed those of passive

treatment. Reference has already been made to spontaneous pneumothorax and tuberculous pleurisy. In addition to these there are pulmonary hemorrhage and metastasis.

*Pulmonary Hemorrhage*—Pulmonary hemorrhage is often insignificant, but it is always a potential source of danger and may result in sudden death. Not infrequently there follows an acute spread of the tuberculosis in the lungs, which may cause death or leave the patient a lifelong invalid. Pulmonary hemorrhage does not occur during pneumothorax treatment when the operation has succeeded in closing the cavity and collapsing the diseased area of the lung.

*Spread of Tuberculosis in the Lungs*—Once tuberculosis has become manifest clinically, its tendency is to spread and involve more and more lung. This may occur by way of the blood stream, the lymphatics or the bronchi. Bronchogenic spread is common and is due in large part to the associated cough. It is frequently the cause of disease in the contralateral lung. Much of this spread can be prevented by timely pneumothorax intervention.

*Metastasis to Other Organs*—Tuberculosis of the lungs may metastasize early in its course to the larynx, intestine or kidneys. It may lead to milary tuberculosis or to tuberculous meningitis. Every tuberculous patient faces the possibility of a spread of the tuberculosis to these vital organs. Timely effective pneumothorax goes far to assure the patient against these complications.

#### SUMMARY

During the past decade, pneumothorax therapy has been applied to an ever increasing number of tuberculous patients, so that today many institutions report 75 per cent or more of their tuberculous patients as receiving artificial pneumothorax treatment. This is in striking contrast to the usual 5 to 10 per cent of five to ten years ago.

The marked enthusiasm for collapse therapy is due in large part to its unique ability to solve many of the pressing problems confronting the tuberculous patient. It often does this in a dramatic and at the same time scientific manner.

It is the most effective single means for the immediate control of the tuberculous toxemia that always accompanies to a greater or less degree the active phases of the disease. With the toxemia eliminated, the patient gains in weight and strength and within a relatively short time is able to take up his daily work again without prejudice to his health. In many instances it offers the one solution to the underlying social and economic problems that are so intimately associated with this disease.

Artificial pneumothorax materially improves the ultimate prognosis. The induced pneumothorax can keep a diseased lung at rest indefinitely, and this accounts for the larger percentage of cures among such patients as contrasted with those treated without pneumothorax. It has been calculated that a patient with moderately advanced tuberculosis, treated with pneumothorax has a chance for ultimate recovery six times as great as the patient treated without pneumothorax.

Artificial pneumothorax is a public health measure of the first magnitude. It is the surest and quickest method for eliminating tubercle bacilli from the sputum and with the establishment of field pneumothorax clinics for the mass treatment of tuberculous patients it has become the solution to the perplexing problem of inadequate hospital facilities and should in time

result in a steady reduction in the mortality and morbidity rates of pulmonary tuberculosis.

Pneumothorax therapy has its dangers and complications, but they can be overemphasized. By and large they are not more serious than the complications of passive treatment and then frequency and severity can be materially reduced by proper technique and management.

The development of selective and simultaneous bilateral pneumothorax has materially widened the indications for pneumothorax therapy and the contraindications have been correspondingly narrowed to relatively few conditions.

In view of all the considerations that have been discussed bearing on the social economic and public health problems of pulmonary tuberculosis and in view of the fact that many more patients will do well and stay well under pneumothorax treatment it would appear that with all the dangers and inconveniences of pneumothorax therapy it is the most efficient method for treating pulmonary tuberculosis in its various stages.

## GASTROSTOMY FEEDING

CLIFFORD C. FRANSEEN, M.D.

BOSTON

A recent review of gastrostomy diets in a number of hospitals has demonstrated that a knowledge of the general principles of such feeding is often wanting. In the smaller hospitals this is perhaps due to the infrequency with which the problem is met. The surgeon passes to the nurse the task of administering a liquid diet of her own selection. This invariably reduces the diet to one of milk with the occasional substitution of egg-nogs prepared even to the vanilla flavoring. Cups of tea or coffee, or beef broths, or malted milk, are often given in unawareness of their low value to a patient in serious need of calories and vitamins. In large hospitals it is customary to feed such patients with a liquid "high caloric mixture" made up of raw eggs, heavy cream, milk and lactose to provide a very unnatural diet in which about 60 per cent of the caloric requirements are satisfied in the form of fats.

My associates and I have prepared a gastrostomy diet from our experience with tube feeding in cases of carcinoma of the mandible, larynx, pharynx or esophagus. After resections of the mandible or larynx, it has often been found desirable to feed the patient by nasal catheter for the first few days after operation until the wound is somewhat healed. In carcinoma of the pharynx, larynx or esophagus, a gastrostomy is often desirable to tide the patient over the period of increased dysphagia at the height of the edema that invariably follows effectual doses of external or interstitial irradiation of tumors in these regions. Relief from the necessity of swallowing food often permits the edematous wall of the diseased esophagus to shrink to a remarkable degree, and the patient may then find it possible to swallow liquid foods again. Patients with carcinoma of the esophagus may be kept properly nourished for a longer period of time on an optimum diet, though all eventually lose weight. Those patients

who are dehydrated or poorly nourished before operation usually gain in weight.

In all these conditions the stomach may be considered as an essentially normal organ except for the presence of the gastrostomy tube and the occasional encroachment of a carcinoma of the esophagus on the cardia of the stomach. Digestion in the stomach may be assumed to be normal except in the occasional case with complete obstruction of the esophagus and total loss of saliva. Chevalier Jackson<sup>1</sup> observed that children with esophageal obstruction being fed by a gastrostomy tube failed to gain in weight until dilatation of the esophagus had been sufficient to permit saliva to pass into the stomach or until the lost saliva was returned by tube. This suggests that the saliva is of considerable importance in the proper digestion of food.

The only barrier to the administration of the ordinary "house diet" is the size of the lumen of the tube; therefore the gastrostomy diet should approximate the normal diet so far as is practicable to the satisfaction of the caloric, mineral, vitamin and fluid requirements of the body. The desirability of a diet with simple ingredients of low cost is obvious. The cost of the diet here outlined has been calculated from current food prices to be between 70 and 80 cents a day.

The use of lactose as a source of carbohydrate in formulas for tube feeding appears to be universal, but I am unable to find any basis for its popularity save tradition. It has been extensively used in high carbohydrate diets administered by mouth, as in diets for patients with typhoid, in which its chief merit lies in the fact that it is less sweet than cane sugar while possessing the same caloric value. Palatability, however, need not be considered in tube feeding. Hosoi, Alvarez and Mann<sup>2</sup> state that "the high percentage of dry residue obtained after giving lactose is of interest because this substance is supposed to be almost unabsorbable by the mucous membrane of the bowel. For this reason it may increase the fluidity of the intestinal contents in much the same way as does magnesium sulfate." The tendency of lactose to produce diarrhea and flatulence is well known clinically. Koehler and Allen<sup>3</sup> in a recent experimental study of the nutritive value of lactose found that from 40 to 50 per cent was lost so far as weight or energy relationships were concerned in the rat. The cost of lactose is appreciable and at present retails at from 50 to 75 cents a pound.

Corn syrup is a very satisfactory and inexpensive form in which the carbohydrate supplement may be obtained and has been used extensively in infant feeding. Several of the simpler sugars are found in this syrup, perhaps a desirable feature in the cases in which there is an absence of salivary digestion.

A very thin cereal gruel of smooth texture is necessary to prevent plugging the tube. Some of the prepared long-cooked cereals marketed for infant feeding fill these requirements and oatmeal is satisfactory if cooked for an hour or more and then strained through a fine strainer. The resulting mucoid cereal mixes well into the feeding mixture and does not settle out even after standing for twenty-four hours.

3 Koehler A. E. and Allen S. F. The Nutritive Value of Lactose. J. Nutrition 8: 377 (Oct.) 1934.

Cracker meal has been tried as a supplementary food, since it has a high caloric value and requires no cooking, but it has an undesirable tendency to form a lumpy mass which settles to the bottom of the mixture. Other meals and cereals, even though finely divided, tend to be granular and also settle to the bottom of the liquid mixture.

Whole milk is a satisfactory liquid vehicle for the diet. Peptonized milk has been recommended for use in gastrostomy tube feeding, but it would seem to be unnecessary to peptonize the milk before administration. Malted milk is too expensive in proportion to its food value.

A large number of raw eggs have been added to the gastrostomy diet in some hospitals, but the experiments of Hosoi, Alvarez and Mann<sup>2</sup> showed that raw egg albumin produced a dry residue of 85.9 per cent in dogs and ran out of the rectum quite unchanged. Cooked eggs are recognized to be more completely

benefits of liver in secondary anemia is not sufficiently convincing to recommend its use for these patients, and its preparation, in small amounts of such consistency that it can be given by tube, will be found to be very trying.

Preparation of the whole day's feeding at a time as a formula mixture, instead of preparing multiple individual feedings, has been transplanted from the current practice in infant feeding. It has seemed desirable, however, to retain one special feeding during the day for the administration of the iron, scraped beef, fruit juice and halibut liver oil. The fruit or tomato juice is a convenient vehicle for the special feeding, and the acidity of the fruit juices has a tendency to curdle the milk if placed in the formula mixture. The halibut liver oil is added to this special feeding to avoid the danger of loss of its small volume. It has been thought safer from a bacteriologic standpoint to give the scraped beef directly in the special feeding rather than to

TABLE 1—Postoperative Diet

digestible than raw eggs and do not produce diarrhea. We have therefore recommended the use of soft poached eggs. Soft boiled eggs would be equally satisfactory but there is a greater chance that they will be cooked too hard. Poached eggs may be pushed through a strainer and, with the addition of a small amount of milk, make a creamy mass that may be added to the diet mixture.

Butter has been used as the supplementary source of fat in lieu of cream, this has previously been suggested by Watson.<sup>4</sup> Fat is cheaper in the form of butter and a quantity may be kept more easily over a number of days. Melted butter emulsifies well in the large quantity of liquid and does not have a much greater tendency to rise to the top than does cream.

Vegetable purees provide a small amount of roughage in the diet, and the desirable elements which greens possess are supplied if spinach is used. The task of preparation of the purees may be obviated by the use of small cans of vegetables marketed for infant feeding. These can be purchased quite as cheaply as small quantities of strained vegetables can be prepared in the home.

We have recommended that beef scrapings, best obtained from "top round" of beef, be given as an additional source of animal protein. Evidence for the

include it in the diet mixture to stand for periods up to twelve or more hours.

Accessory factors have been adequately provided in the diet. Supplementary vitamins are given in the form of halibut liver oil, brewers' yeast and orange, grapefruit or tomato juice. The use of halibut liver oil has seemed to eliminate the objectionable regurgitation complained of by some patients when cod liver oil is used. Supplementary iron is given to delay the secondary anemia that inevitably occurs in the patients with advanced carcinoma. This has been given in the form of a 50 per cent solution of ferric ammonium citrate, but ferrous sulfate crystals may be used as an alternative. From table 2 it may be seen that the established daily requirements for calcium, 0.68 Gm, for phosphorus, 1.32 Gm, and for iron, 0.015 Gm, have all been generously satisfied. Copper, cobalt and manganese, and the essential amino acids, as well as vitamin E and iodine may safely be omitted from particular consideration in this diet.

None of our patients have developed a diarrhea on this diet nor have any complained of flatulence, in contrast with our previous experience with the "high caloric mixture." A patient has occasionally developed a mild degree of constipation and been relieved by the addition of a small amount of prune juice to one of the feedings each day. Laxatives or liquid petrolatum may be added to the feedings when indicated.

<sup>4</sup> Watson W L. Routine Management of the Gastrostomy Patient. New York State J Med 33: 1261 (Nov. 1) 1933.

PREOPERATIVE AND POSTOPERATIVE CARE

In the preoperative preparation for gastrostomy, patients who are dehydrated and malnourished from inability to swallow are given 10 per cent dextrose in physiologic solution of sodium chloride by the slow drip method for a few hours. No more than a small dose of morphine sulfate is necessary as preoperative medication.

In our clinic the Witzel type of gastrostomy with a size No. 22 soft catheter is invariably done under local anesthesia, and the tube is allowed to remain in place except for periodic removal for cleaning or replacement. This provides a tube large enough to admit a rather viscous feeding mixture when reasonable care has been taken in straining the ingredients during preparation. The feeding mixture here described, how-

route for the absorption of any appreciable amount of dextrose.<sup>5</sup>

After operation we have delayed the use of cereal and vegetables until the full diet is adopted in order to obviate the labor of preparing small amounts of these ingredients, as well as to eliminate the possibility of plugging the tube with improperly prepared material during the early period when replacement of the tube would be somewhat hazardous.

On the first day after operation the patient is already receiving about 1,166 calories, and the caloric value then advances rapidly each day to make up the temporary deficit. The quantity of the feedings is gradually increased if the patient experiences no distress, and the number of the feedings is decreased. By the eighth day the full diet mixture can be used. In some patients

ever, is of sufficiently smooth texture so that it can be used for feeding through a nasal catheter of small caliber.

We have prepared an outline for the simple preparation of feedings for the patient during the immediate postoperative days preceding the adoption of the full diet. The amounts used are very conservative, and many patients may be advanced to the full diet more rapidly than here outlined. Memory of the diet by the nursing staff is facilitated by the parallelism of days and the amounts of the feedings, i.e., 3 ounces on the third postoperative day, 5 ounces on the fifth postoperative day, and so on.

We have recommended nothing by tube for twenty-four hours to permit the sinus tract to be walled off by fibrin. Supplementary parenteral fluids are required during the first three days to maintain an adequate fluid intake. We prefer to give these as a slow intravenous drip of 10 per cent dextrose solution, but hypodermoclyses may be substituted or physiologic solution of sodium chloride, or tap water may be given by rectum. We have found, however, that many of the elderly patients operated on do not retain fluids administered by rectum. Experimental evidence suggests that no reliance should be placed on the rectal

requiring a greater food or fluid intake, the amount or the number of the feedings may be further increased, or additional water may be used with the feedings. On the other hand, by proportionately decreasing the number or the quantity of the tube feedings, the diet can easily be modified for the patient who is able to take small amounts of nourishment by mouth. When the caloric requirements are satisfied by tube, the patient may relish thin, clear, beef broths by mouth which, though very tasty, provide only 1 calory per gram of the dried beef cube.

We have been able to maintain an adequate intake without disturbing the patient during the night, and have not found it necessary to exceed a volume of 11 ounces for the individual feedings, i.e., 10 ounces of the feeding mixture followed by 1 ounce of water. This gives a total fluid intake of 77 ounces a day. Many patients find that there is a leakage about the tube with larger feedings or that there is abdominal distress even though the diet mixture is administered slowly.

The presence of the tumor mass in the esophagus tends to excite the esophagosaltary reflex by which a

5 Ebeling W W Aborption of Dextrose from the Colon Arch Surg 26 134 (Jan) 1933

face flow of saliva is produced to wash away any bolus of food held up in the esophagus. During the waking hours the saliva is swallowed, or expectorated when the obstruction is complete, but when the patient is falling asleep the accumulation of saliva often causes him to wake up choking when it has overflowed into the trachea. At such times marked relief can be obtained by the use of small subcutaneous doses of atropine sulfate, or a dual effect of diminution of the salivary secretion and of sedation can be obtained by the use of scopolamine hydrobromide.

Feeding is most satisfactorily accomplished by the use of a syringe of the Asepto type, the barrel of which can be used as a funnel. If the formula mixture should not flow in satisfactorily by gravity, the rubber bulb can be attached and light pressure applied.

The details of the diet are reviewed with the patient or some other member of his household, and he is provided with the following instruction sheet at discharge.

#### INSTRUCTIONS FOR GASTROSTOMY FEEDING

Prepare one cup of oatmeal, using 2 level tablespoonfuls of dry oatmeal cereal in a cup of water. Cook in a double boiler for at least one hour, preferably two, then strain through a fine strainer into a container having a mark to indicate a level at  $7\frac{1}{2}$  cups (use accurate measuring cup).

Add

- $1\frac{1}{4}$  cup of corn syrup (dark)
- $\frac{1}{4}$  cup or 4 tablespoonfuls of melted butter
- $\frac{1}{4}$  cup or 1 small can of strained baby vegetable puree, preferably spinach
- 1 heaping tablespoonful of brewers yeast powder and
- 1 level teaspoonful of table salt

Poach five eggs lightly and push through a fine strainer. Stir a small amount of milk into the strained egg until it is of a thin creamy consistency and then add to the feeding mixture.

Add enough pasteurized milk to bring the total volume up to the mark previously made at  $7\frac{1}{2}$  cups.

Place in refrigerator.

To use

Stir the mixture. Pour off  $1\frac{1}{4}$  cupfuls into a small container and warm lightly. Give the mixture through the tube using an Asepto syringe barrel or a funnel. Follow with 1 ounce of water to clean the tube.

Special Feeding

At 10 a. m. add slowly two thirds of a cup of strained orange, tomato or grapefruit juice to 2 tablespoonfuls of beef scrapings (best obtained from top round of beef). Stir constantly or beat to prevent the formation of lumps. Strain to remove any meat shreds which may plug the tube. Add 1 teaspoonful of the prescribed iron solution and 10 drops of halibut liver oil. Give the mixture through the tube, using the syringe barrel or a funnel. Follow with 1 ounce of water.

Feeding schedule

1 Give  $1\frac{1}{4}$  cupfuls of the feeding mixture at 8 a. m., 12 noon, and at 2, 4, 6 and 8 p. m.

2 Give the special feeding at 10 a. m.

Feedings should be given with the patient lying down, and the patient should remain on the back or right side for fifteen minutes following each feeding.

The patient may take additional water or clear broths by mouth when he is able to swallow them.

The tube should be kept in place at the same depth at all times unless it becomes plugged. If this occurs, loosen the fastenings and withdraw the tube. Clean the tube and force water through it with the syringe. Lubricate the tip with liquid petrolatum and reinsert the tube gently to its original depth and replace the fastenings. If any resistance is met with do not force the tube in but call your family physician or return to the hospital at once for assistance. The tube should not remain out for more than a short while. Return to your physician or to the hospital at least once a month for examination and for replacement of the tube.

695 Huntington Avenue

## GALLBLADDER CONTRACTILITY AFTER BLOOD TRANSFUSION

RALPH BOERNE BETTMAN, MD

Associate Professor of Clinical Surgery, Rush Medical College  
AND

WILLIAM J. TANNENBAUM, MD

Adjunct Surgeon, Michael Reese Hospital

CHICAGO

Philip Sandblom of Sweden in 1933 apparently completed the explanation of the method of gallbladder contraction. Evarts Graham, using what now is called the Graham-Cole method of cholecystography, proved conclusively that the gallbladder contracted. Ivy isolated his cholecystokinin from the mucosa of the duodenum of dogs and demonstrated that the contraction is initiated by a hormone.

Sandblom apparently proved that this hormone is transmitted through the circulating blood, by demonstrating that the gallbladder in fasting individuals contracted following the reception of blood from a donor who had previously eaten a fat meal. This work seemed to us of tremendous importance. Using his conclusions as a basis, we decided to continue the experiment along the following lines. We wished to see, first, whether the human equivalent of cholecystokinin was carried in the blood serum or in the cellular structure, secondly, if it was carried in the serum whether it might be possible to concentrate the serum so as to isolate the hormone, thirdly, whether the contraction in human beings was due to a hormone at all or simply to the high fat content of the blood serum, and, finally, whether it would be possible to get a concentrate of such strength that, by means of small doses, we would have a method of producing gallbladder contraction which would be of both clinical and experimental value.

The first step of the work consisted in obtaining high fat content blood serum and watching its effect on the emptying time of the gallbladder. In brief, the experiment was conducted as follows. Nine normal, healthy individuals with negative Wassermann and Kahn serum reactions, who presented themselves to the Serum Center of the Michael Reese Hospital, were chosen. These patients reported in the morning without breakfast and were given 8 ounces (236 cc) of a meal consisting of 32 per cent cream, 2 egg yolks, 1 teaspoonful of sugar and 1 teaspoonful of cocoa. Blood was drawn from an hour to an hour and a half after the ingestion of this meal. The blood was allowed to clot, the bottles were then placed in centrifuge, and the serum, without separation of the fat, was withdrawn and pooled. The resultant serum in each case was thick and milky white and when tested for fat showed a four-plus, three-plus or two-plus reaction. Tricresol was added and the serum then kept under sterile conditions in 100 cc bottles in the icebox.

N. R. was selected for the test, Dec 5, 1934. A cholecystograph, which had been made a week previously, showed a good concentration of the dye and a normal emptying of the gallbladder, although one large calculus was found to be present. (Choosing of a patient with a gallstone was premeditated because it was intended, should the gallbladder empty, that the test be repeated later at the time of operation and the gallbladder contraction actually visualized while the abdomen was open.) The patient was given gall

Read before the Society of Internal Medicine, Dec 16, 1935.  
From the Group for the Study of Diseases of the Biliary Tracts of Michael Reese Hospital.

bladder dye on the evening of December 4 and in the morning the film showed a large distended gallbladder, good concentration of the dye, and a single calculus. One hundred cubic centimeters of high lipid serum was given intravenously, and films taken ten minutes, one-half hour, one hour and two hours later showed that the gallbladder still retained approximately its original shape and opacity. After two hours the usual fat meal was given, and films taken an hour later showed that the gallbladder had evacuated. Thinking that perhaps the failure to obtain gallbladder contraction might be explained on the basis of an insufficient amount of serum, we repeated the test.

In the second case the gallbladder had shown a normal concentration and emptying on previous x-ray studies. M G was given the usual amount of dye on the night of December 17, and a picture taken fourteen hours later, with the patient fasting, showed a good concentration of dye and an apparently normal, well distended gallbladder. Two hundred cubic centimeters of high lipid serum was given intravenously and the gallbladder failed to contract, as shown by x-ray studies, ten minutes, one-half hour, one hour and two hours afterward. Two and one-half hours later the patient was given egg yolk by mouth, and it was found that the gallbladder then emptied normally.

These first two experiments clearly indicated that 200 cc of high lipid serum, obtained from individuals who had eaten a fat meal, failed to produce an emptying of the gallbladder, although in both instances it was shown that the gallbladder did function normally by the fact that after the ingestion of the usual fat meal the gallbladder emptied in the normal manner.

At this stage it became obvious to us that we had perhaps been in error in accepting the work of Sandblom and that it would be necessary to repeat his original experiments. The following two experiments are typical of the seven which we conducted to prove or disprove his contentions.

Jan 10, 1935, W G, who had on previous x-ray investigation been shown to have a normally filling and emptying gallbladder, was chosen because it had been contemplated to give this patient a blood transfusion before performing an exploratory laparotomy for a possible carcinoma of the sigmoid. The night of January 9 the patient was given the usual amount of gallbladder dye. A roentgenogram taken after fourteen hours, with the patient fasting again, showed a well filled gallbladder with normally concentrated dye. The patient's brother, who was to act as donor, was given a breakfast consisting of 6 ounces (180 cc) of cream and the yolks of two eggs. An hour and a half later 500 cc of blood was transfused from this donor into the veins of the patient by the multiple syringe method. Roentgenograms taken fifteen minutes, one-half hour, one hour and two hours later failed to show any contraction of the gallbladder. The patient was then given the fat meal, and roentgenograms taken at intervals thereafter showed the normal emptying responses an hour later.

S O presented a questionable diagnosis. Previous roentgenograms had shown that the gallbladder filled, concentrated and emptied normally. In the fourth experiment roentgenograms taken on the morning of May 20 while the patient fasted fourteen hours after the ingestion of gallbladder dye, showed normal filling and concentration of the gallbladder. At 8:40 a.m. the donor was given a fat meal of 6 ounces of cream and the yolks of two eggs. At 9:35 this meal was

repeated. At 10:10, 500 cc of blood was withdrawn by multiple syringe from the donor and injected into the veins of the patient. Roentgenograms fifteen thirty and sixty minutes later showed no contraction of the gallbladder. At 11:30 the patient was given a fat meal by mouth and at 12:30 the gallbladder was empty.

Five more experiments were identical except that the blood transfusions were done at slightly different intervals, varying from thirty-five minutes to an hour and ten minutes after the donor had received a fat meal. In each instance it had been established previously that the various subjects in question had normal functioning gallbladders. In none of the seven patients did the reception of 500 cc of fresh blood, taken from donors who had had a fat meal from thirty-five minutes to one and one-quarter hours previously, cause any clearly demonstrable contraction of the gallbladder, and in every instance it was shown that the normal gallbladder responses were present, by the fact that after the subject himself or herself had eaten a fat meal the gallbladder emptied.

#### CONCLUSION

From these experiments, we must conclude that

1. High lipid content serum in amounts of 100 and 200 cc fails to cause gallbladder contraction.
2. The transfusion of 500 cc of blood from a patient who has first been given the usual so-called gallbladder fat meal fails to produce demonstrable gallbladder contraction in the recipient.

### DELINQUENT PATIENTS IN VENEREAL DISEASE CLINICS

#### RESULTS OF A STUDY IN BALTIMORE CITY HEALTH DEPARTMENT

FERDINAND O. REINHARD, M.D., C.P.H.

Director, Bureau of Venereal Diseases

AND

W. THURBER FALES, Sc.D.

Director, Bureau of Vital Statistics

BALTIMORE

In the summer of 1935 it became possible to make a survey of the activities of the venereal disease clinic of the Baltimore City Health Department because of clerical assistance furnished by the Baltimore Emergency Relief Commission. In that study an attempt was made to evaluate the effectiveness of the city clinics from the standpoint of curtailing the spread of syphilis. A detailed analysis was made of all new patients admitted during the period beginning July 1 and ending Dec 31, 1933.

In order to draw any conclusions from this study it will be necessary to outline briefly certain facts concerning the venereal disease clinics in Baltimore in 1933. During that year 4,558 new cases were admitted, of which number 2,595 were of syphilis. A total of 102,352 visits were made to the clinics. In 1931, two years previously, a total of 2,109 new cases had been admitted. Of these, 1,383 were new cases of syphilis, and 57,043 visits to the clinics were recorded. Thus there had been in 1933 an increase of 118 per cent in total admissions and 79 per cent in the total number of visits to the clinics as compared with the year 1931. Prior to 1933 the venereal diseases had been under the control of the Bureau of Communicable Diseases. At that time a bureau of venereal diseases was established.

Prior to the organization of the bureau there had been little attempt to follow up delinquent patients or to determine sources and contacts of new cases and bring them under treatment. No special effort had been made to keep syphilitic mothers under continuous treatment during pregnancy, nor had arrangements been made for Wassermann tests in the case of their children. It was nevertheless felt that a study of the clinic histories of patients admitted during the latter half of 1933 would form a base line for future comparisons, as the patients admitted during that period had had ample time to complete treatment by July 1935.

#### SOME BASIC FACTS IN THE CONTROL OF SYPHILIS

It is well established that in primary and secondary syphilis

1 The earlier a diagnosis is established and prolonged treatment instituted, the better are the chances of curing the patient

#### EARLY LATENT CASES

In Baltimore the term "early latent" applies to those cases which do not come under treatment until after the completion of the secondary period but do so before three years after the original infection. It can be taken for granted that in these a natural immunity has developed to the maximum degree. Consequently, the danger of injuring these patients by an insufficient number of treatments is not so great. However, treatment should be given to this group for the maximum period of time and with as much regularity as can be reasonably obtained.

#### LATE LATENT CASES

In the late latent group are found those cases of syphilis in which three years has elapsed since the development of the primary chancre or secondary manifestations and in which the Wassermann reaction is still positive, owing to insufficient treatment. From the standpoint of infectivity these cases are of much less direct interest to the public health officer. They con

2 If no treatment is taken by the patient a certain amount of immunity is developed, up to the completion of the secondary stage, and incomplete treatment, if begun prior to the end of the secondary period, prevents or destroys the development of natural immunity by the host and thereby makes the patient more susceptible to infectious relapses and to the development of serious late lesions of the cardiovascular and cerebrospinal systems.<sup>1</sup>

From the last statement it should not be inferred that anything is gained by putting off treatment until the secondary stage is past. On the contrary, every effort should be made to begin treatment, if possible, in the seronegative stage when the diagnosis is based on a darkfield examination. It is important that once treatment is begun in an early case it be continued to completion. The practice current in the past by which it was thought that a few treatments sufficient to clear up the infectious lesions would protect the community is reprehensible in the face of modern knowledge.

stitute a great social and economic problem, however. From 12 to 15 per cent of the inmates of asylums are recruited from this group. Furthermore, from 10 to 12 per cent of these patients are incapacitated by the cardiovascular complications of the later years. These cases present special therapeutic problems for the practitioner of medicine. Intelligent treatment would make it possible to arrest the development of untoward symptoms and enable these people to earn their living. In this manner it should be possible to save millions of dollars to the taxpayers of the future. Further than this statement of the problem, no attempt will be made to consider the late latent group in this article.

#### THE AIMS OF TREATMENT

Following the time when the Wassermann reaction becomes permanently negative, the goal established for ideal treatment should be not less than four alternating courses consisting of eight weekly injections of an arsenical and eight weekly doses of a heavy metal. Without reaching this ideal goal, and viewed from the

1 Moore J. E. Modern Treatment of Syphilis. Springfield, Ill. Charles C. Thomas, 1933. pp. 26, 28.

standpoint of safety from future infectiousness, the minimal optimal treatment should not be less than twenty doses of an arsenical and twenty doses of a heavy metal, taken at weekly intervals in interchanging courses of eight doses each. It follows, then, that the number of patients who receive the minimal optimal number of treatments constitute the criterion by which the effectiveness of a treatment clinic service can be gauged.

There follows an analysis of the number of treatments received by patients admitted during the period July-December 1933. It is presented in order to show to what extent the venereal disease clinics of the Baltimore City Health Department were then discharging their responsibility.

#### RESULTS OF THE STUDY

From table 1 it will be seen that the minimal optimal number of treatments (forty) were received by more than one half of the white patients as against one third of the colored group. The contrast between the percentages of patients receiving various numbers of treatments, white and colored, lies primarily in the percentages of patients receiving less than eight treatments.

Colored males were more commonly lost because of change of location and for lack of cooperation than white males and females. No reason is known for the loss of 40 per cent of all cases. A study of the histories frequently showed that lack of cooperation, the age of the patient and the stage of the disease to a certain extent explained many of these delinquents. It is interesting to note in table 2 that there was no apparent reason for the loss of 44 per cent of the primary and secondary white cases.

Table 4 shows that among the patients with primary and secondary lesions who continued treatment at the clinic until the minimal optimum of forty treatments was received, there were twice as many white males and females as colored males and females. White patients with latent syphilis did not continue treatment for such a long time as white patients with primary and secondary lesions. On the other hand, both colored males and females with latent syphilis continued their treatments longer than patients of the same race with primary and secondary lesions. In the case of colored males with latent syphilis, nearly as high a percentage received forty or more treatments as did white patients.

No reason given	41	103	122		41	20	61		358		81	32	43	21	21	52	126	43	423	107	74	63	29	29	23	26	10	266

and those receiving sixty-four or more. For white patients, roughly one fourth received the full course of treatments, in colored patients, about one fourth dropped out before receiving eight treatments.

There is very little difference in the number of treatments received by males and females of the same race. However, in the group that received less than eight treatments are found twice as many white women and three times as many colored males and colored females as white men.

Tables 2 and 3 present an analysis of the number of treatments received by patients who did not complete their four courses of treatment, classified according to their status as to clinic attendance in July 1935. A comparison of these two tables shows that the proportion of white patients with primary and secondary lesions who had not completed full treatment and were still attending the clinic was the same as the proportion of white patients with latent syphilis. This situation holds also for colored patients with primary and secondary lesions as compared with colored patients with latent syphilis. For the first group (white males and females) 28 per cent remained under treatment and for the second group (colored males) 17 per cent. In the case of colored females however 34 per cent of patients with primary and secondary lesions remained under treatment as compared with 26 per cent of patients with latent lesions.

with latent syphilis. The figures are 40 per cent for the colored males and 46 per cent for the white males and females.

#### COMMENT ON TREATMENT

This detailed study of clinic attendance tends to point out the weak spots in the clinic and field setup.

TABLE 4—*Percentage of Primary, Secondary and Early Latent Cases in Which Forty or More Treatments Were Given Classified by Color and Sex*

Group	White Male and Female	Colored	
		Male	Female
Primary and secondary Latent	53.4 46.6	2.6 40.0	25 71.1

and shows where emphasis should be placed in order to improve conditions.

A special effort must be made to have regular treatments given in the primary and secondary infectious cases until lesions have cleared up and they become temporarily noninfectious. After this has been accomplished every effort must be made to enforce weekly treatments to the completion of four courses, if possible, and in all cases to the point at which at least the minimal optimum of forty treatments have been received. Colored males and females in the primary and secondary groups should be given special attention.

In dealing with early latent cases at least twenty treatments of an arsenical and twenty of a heavy metal must be insisted on as minimal treatment. In addition, every effort should be made to have the patient take even more complete treatment. Extreme regularity of treatment, while desirable, is not quite as important as in the case of patients with infectious lesions.

#### IMPROVEMENTS IN THE FOLLOW-UP SYSTEM

At the present time (1935) five full time social investigators are connected with the Bureau of Venereal Diseases. They consist of three white women, one colored woman and one white man. These workers, besides visiting delinquent contacts, also spend time in the clinics interviewing new patients with the hope of finding sources and contacts of cases.

During seven months beginning February 1935 there were 6,187 delinquent patients reported from the five clinics, an average of 884 per month or about 221 per week. In addition, delinquents not receiving treatment reported by local hospitals and private physicians were visited by the social workers.

At present the histories of all primary and secondary cases absent from the clinic one week and all histories of early latent cases absent on two occasions are sent to the bureau director's office by the clinic clerk at the end of each week. These are carefully scrutinized by the director and any points of special interest are noted. They are then distributed among the workers on a district basis. Patients with primary and secondary lesions and pregnant women are given first consideration. These are visited personally by the investigators. In other cases, when the patient is not found at home, a card is sometimes left advising him or her to return to the clinic. In case the patient has changed his address, the name is reported to the chief inspector in the police department and is in turn given by him to the district police officer, who attempts to locate the patient. All new addresses are reported back to the Bureau of Venereal Diseases and are given out to the social investigators the following week.

Patients who repeatedly do not respond to the visits are finally summonsed to a police magistrate's court, where they are given a warning, which often brings results. In early clinical cases, summonses are issued after the patient has been absent from the clinic on two occasions and in early latent cases after they have been visited three or four times without results. In addition to the visits made by the social workers, form letters or personal letters are sent on occasion by the director of the bureau. These attempt to explain to the patients the dangers of discontinuing treatment and always include a special informative pamphlet. It has been found that letters are about 40 per cent effective. The results are comparable to visits in which the patients are not personally interviewed. All patients who prove to be hopelessly uncooperative are discharged by the director of the bureau. A final letter of explanation and advice is sent at this time.

In the case of contacts, who are also visited by the social investigators, the problem is if anything more difficult. Here persuasion alone must be relied on, as it is impossible to summons a person to a police court in whom the diagnosis of syphilis has not been made. Explanatory letters and printed circulars are often useful.

By following out the methods just described, we hope that in the future the minimal optimal number of treatments will be received by an increased number of

patients and also that more patients will complete their four courses of treatment. A comparative study made after the lapse of from one to two years should show definite improvement.

#### SUMMARY

A study of the delinquency of venereal disease clinic patients in continuing their treatment has been made in order to furnish a base line for future comparisons. While it is not possible to estimate exactly the extent to which a venereal disease clinic service of a city health department discharges its responsibility, this study presents preliminary evidence on that problem.

City of Baltimore Health Department

## THE TREATMENT OF DYSMENORRHEA WITH INSULIN

#### PRELIMINARY REPORT

ALEXANDER ALTSCHUL, M.D.

Associate Visiting Physician Harlem Hospital

NEW YORK

Primary or essential dysmenorrhea has been correctly described as the *bête noire* of gynecology. All the skill, knowledge and ingenuity of the general practitioner and gynecologist are taxed to their capacity in the management of this distressing symptom complex.

A thorough gynecologic examination frequently reveals no pelvic abnormality, and as Novak and Reynolds<sup>1</sup> aptly remark, "the intelligent treatment of this disorder [besides a complete pelvic examination] can never be restricted to the pelvis alone and must include a thorough study which may carry the physician far afield into the domains of internal medicine, endocrinology, psychiatry and other branches of clinical investigation."

The remedies recommended and the procedures adopted are legion. Surgery, such as operations on the cervix (Dudley, Blair Bell, Pozzi), dilation without curettage and dilation with curettage are frequently resorted to. The benefits obtained sometimes give temporary relief over the next few succeeding periods and only occasionally give permanent relief. Alcohol injections of the sacral nerves have been used.<sup>2</sup> There are many references in the literature to the use of laparotomy for resection of presacral sympathetic nerves and for oophorectomy in an effort to give the patient much needed relief,<sup>3</sup> and more recently x-ray and radium exposures have been used to induce sterility and an artificial menopause.<sup>4</sup>

Without being hypercritical of the success obtained with such extreme measures, I would point out that it is quite apparent that not every patient with dysmenorrhea will submit to surgery or to the induction of sterility. On the other hand, one must realize the great suffering of these unfortunate women and the extreme

measures that they will frequently permit to give them more or less permanent relief. In addition, there is an economic factor which must not be overlooked. Besides the loss in earning power, the embarrassment that they suffer as a result of their periodic incapacity is often the origin of grave psychoneuroses.

The patients with primary dysmenorrhea, excluding those with organic conditions, may be grouped into four main classes.

A In the first group are those with a hypoplasia (subpubescence of the uterus, with a predominance of the fibrous elements over the muscular). Therapy should be aimed at the development of the uterus, and in these the use of a sex stimulating hormone is indicated.<sup>6</sup>

B In the second group are those in whom, according to Novak and Hartnik,<sup>6</sup> the dysmenorrhea can be explained on the basis of an anxiety psychoneurosis.

C Another group of patients is hypersensitive to pain stimuli, and what the normal individual would consider only slight or moderate pain produces severe reactions in this group.

D There is a distinct group in which endocrine disorder is the cause of the trouble. Novak and Reynolds<sup>7</sup> believe that the cause of dysmenorrhea is an exaggerated contraction of the uterus and not a mechanical obstruction, as was formerly believed. They have shown that follicular hormone stimulates uterine contraction and that progesterin inhibits it. They therefore recommend the luteinizing principle from the urine of pregnant women to stimulate progesterin formation and so indirectly inhibit the rhythmic contraction of uterine muscle.

Novak<sup>8</sup> does not favor the use of estrogenic substance empirically or on the basis of Kennedy's theory<sup>9</sup> that the symptom is due to degenerative changes in Frankenhauser's ganglion due to diminution of estrogenic substance. On the contrary, Novak<sup>10</sup> says that the estrogenic substance is the natural stimulant of uterine contractility, and that progesterin, or the anterior pituitary-like principle, is the inhibitor of uterine contractility. He recommends follutein or antuitrin S, from 100 to 200 units each day for several days before the flow. Novak, however, is not enthusiastic about its results and says that "because of the ever present psychic factor it is difficult to appraise the effect."

In the course of my use of insulin for its metabolic stimulating effect in malnutrition, patient 1, who had always been obliged to go to bed for the first two days of her menstrual period, reported entire absence of pain while under treatment with insulin. During and after the war, in Germany and in Austria, the population suffered from lack of food, especially vitamin and mineral bearing elements, with resultant malnutrition and concomitant functional endocrinopathies. The women in these countries suffered from severe dysmenorrhea as well as from amenorrhea. Mindful of these facts it appeared to me that the favorable effect of insulin in this patient was due to improvement in nutrition and so indirectly menstrual relief on a constitutional basis. However, I decided to see its immediate effect on a patient during an attack of dysmenorrhea.

Patient 2 consulted me May 16, 1935, for a severe attack of menstrual pain of twelve hours' duration. She had come in from a midwestern city that day. In order to avoid the possible improvement that might result from suggestion, it was explained to the patient that the remedy being used might not give relief and was not certain in its effect. Fifteen units of insulin commercial brand C, was given at 2 p. m., followed by liberal quantities of orange juice. In thirty minutes there was complete relief from pain. For the next six hours the patient felt hungry and slightly nervous. She was able to get about. She had always suffered with severe pain for two days of her period, requiring bed rest.

In order to avoid the criticism that the stimulation of sex development and function with the use of insulin was due to the improvement of diabetes, G. A. and R. L. Williams<sup>11</sup> report a case of striking acceleration of body growth and sexual development in a non-diabetic girl, aged 8½ years. While using insulin they noticed an increase in the size of her breasts and periodic abdominal pain simulating menstrual cramps. These effects disappeared when insulin was discontinued and reappeared months later when insulin was resumed.

Without going far afield into the endocrinology of the pancreas and the possible effect of insulin on the other glands, the fact remains that other observers have noted endocrine effects other than stimulation of carbohydrate metabolism by insulin.

In this series of cases, patients were arranged in two groups. Group A, treatment from five to seven days before menstruation, and group B, treatment during the attack. The effects were noted with insulin prepared by different manufacturers, and a definite variation was observed.

CASE 1—Mrs. M. S. K., aged 26, never pregnant, a former entertainer, consulted me April 15, 1935 for nausea, inability to gain weight, and a chronic cough. She had had lobar pneumonia type V in October 1933, with uneventful recovery except for bouts of coughing since and before the pneumonia. There was no family history of dysmenorrhea. The menses began at 13, occurred every twenty-eight days and she flowed five days, with severe pain requiring bed rest the first two days. She had had several attacks of sinusitis, with an operation for the removal of polyps.

The patient was poorly nourished, was 147 cm. tall and weighed 34.5 Kg. The heart was normal. The lungs showed moist rales at both bases. The blood pressure was 90 systolic, 70 diastolic. Both kidneys were palpable. There was a small uterus in normal position. The adnexa were normal. Examination of the central nervous system was negative.

Laboratory examination showed hemoglobin, 78 per cent (Sahli); red blood cells, 4,100,000, white blood cells 7,320, differential, normal. The urine was normal. The blood Wassermann reaction was negative. The Ewald test meal (one hour) showed free acid 40 cc., total acid, 68 cc. Blood sugar (fasting) was 0.68 per cent. The basal metabolic rate was minus 5 per cent. The sputum was repeatedly negative for tuberculosis. A gastro-intestinal series of roentgenograms showed visceropeliosis and otherwise were negative. Roentgenograms of the chest showed increased markings at both bases, on the left more than on the right. Roentgenograms of the sinus showed right clouding of the ethmoids and antrums.

Treatment consisted of supporting treatment and insulin, 10 units once daily before the noon meal. After two and one-half weeks of treatment the weight improved to 37.3 kg.

At the menses April 25 there was no pain and only slight discomfort, the patient was up and about.

CASE 2—Mrs. B. C. aged 24, never pregnant, had had pneumonia three times, measles, chickenpox, pertussis and an appendectomy at 12. The menses began at 13, and were for

five to six days' duration, every twenty-nine to thirty days, with severe pain the first day. The basal metabolic rate, Aug 24, 1934, was minus 11 per cent, blood sugar, 0.96 mg.

The patient was poorly nourished and had a faint systolic murmur at the apex, not transmitted. She weighed 47.3 Kg. The blood pressure was 120 systolic, 80 diastolic.

May 16, 1935, she had come into New York from a mid-western city and had severe abdominal pain with menstruation. Fifteen units of insulin, commercial brand C, followed by a liberal quantity of orange juice was given. There was relief in thirty minutes with no further pain during this period. The patient returned to her home in the Middle West.

CASE 3—L. G., aged 19, single, a clerk, had an uneventful family history. The menses began at 14, were irregular, every twenty-eight to thirty-five days, with moderate flow of five days' duration, there was severe pain the first two days. She weighed 40 Kg and was 159 cm tall.

Physical examination was negative. The basal metabolic rate was minus 12 per cent. There was no rectal or pelvic abnormality. There was no family history of dysmenorrhea.

Treatment was begun June 13, 1935, with 12 units of insulin, commercial brand B, daily, and on June 27 was changed to 10 units twice a day (self administered). Her weight, June 22, was 41 Kg.

She came to the office for insulin while menstruating, there was no pain or discomfort. July 25 was the next period, with self administration of insulin, there was no pain and she was comfortable. Since discontinuance of the insulin she has had some pain, not always as severe as before treatment was begun.

CASE 4—L. P., aged 25, a secretary, had the onset of the menses at 14. The periods were somewhat irregular, every thirty to thirty-five days of five days' duration, with excruciating pain the first two days.

Physical examination was essentially negative. Her weight was 55.4 Kg and her height 162 cm. The blood pressure was 105 systolic, 85 diastolic. Blood sugar was 0.92 mg. The blood count was normal.

She was treated July 1, 1935, five days before her period, with from 7 to 10 units of insulin, brand B. The period of July 6 was attended with very slight discomfort, and she worked. In August while on her vacation she had no treatment and there was severe pain. September 6 she took daily injections of 7 units of insulin B for four days and was comfortable. October 6, she had one injection of 7 units before the period (five days early). There was pain with the period, 5, 7 and 7 units of insulin was given during the first day and on the second, with relief after forty-five minutes. November 9, the period began. She had had insulin, 7 units daily for five days, before the period. There was slight pain, urticarial wheals appeared with the injections. December 16, 10 units was given with the onset of pain, with total relief in one-half hour.

CASE 5—G. T., aged 33, single, formerly an entertainer, an American, with no family history of menstrual pain, had been operated on in 1931 for salpingectomy and partial oophorectomy for bilateral salpingo-oophoritis, and in 1934 for intraligamentous cyst, i. e., "chocolate cyst" of the ovary. Menstruation was very painful before and after operation, it occurred every twenty-eight days, before operation the flow was from ten to eighteen days. The basal metabolic rate was plus 12 per cent. The blood sugar was 102 mg.

Ten units of insulin twice a day was given for appetite stimulation and weight increase, from July to September 1935. During the course of treatment the menstrual periods were painless.

CASE 6—L. R., aged 12½ years, a school girl, whose menses began at 10½ years, had a period every twenty-eight days of five days' duration, the first two days of which were extremely painful and the patient would be bedridden.

She had had measles and pertussis, a tonsillectomy at 6 and an appendectomy at 10. The child's mother was a cardiac patient but did not have menstrual pain.

Physical examination revealed rheumatic heart disease with a double mitral valve. Rectal examination showed no pathologic pelvic condition.

July 31, 1935 insulin brand C was begun and 6 units was given daily for five days preceding the period August 5 at which time the child was at play and reported absence of pain.

At the September 4 period insulin brand A, 6 units daily was given, there was some pain. For the next period, October 6 administration of insulin C, 6 units, was made by the mother daily for one week before the period. There was entire relief of pain and the patient was comfortable. In November the patient was out of town, a letter received from her told of administration by the mother daily for four days before the period followed by very slight discomfort "hardly enough to talk about." In December she was still out of town, a letter, received on the 9th reported daily administration by the mother for six days preceding the period and total relief from pain.

CASE 7—M. J., aged 19, a typist, had periods every twenty-eight days for five days. Weighed 52.5 Kg, and was 163 cm tall. Blood pressure was 95 systolic, 70 diastolic.

Laboratory examination showed hemoglobin, 70 per cent, red blood cells, 3,990,000, white blood cells, 7,950, with differential normal, blood urea, 14.1 mg per hundred cubic centimeters, creatinine, 1.3 mg, sugar 84 mg, sugar tolerance test, normal (two hours).

July 20, 1935, insulin, brand C, was given for four days resulting in only slight pain with the period. August 18 insulin brand A, 7 units daily for eight days delayed the period three days and resulted in severe headache and no relief of pain. At the November 14 period there was no pain. Insulin brand C, 10 units, had been given for three days before the period.

CASE 8—D. H., aged 23, a stenographer, weighing 51.7 Kg and 166 cm tall, menstruated every twenty-three days, for five days, with excessive flow. Rectal examination showed no definite pelvic disorder.

Insulin, brand A, 8 units daily for one week, delayed the period three days, there was headache and no relief. During the period beginning Sept 30, 1935, 10 units of insulin was given with temporary relief after one hour. The pain recurred in six hours. Relief was again obtained after one hour.

CASE 9—A. E., single, aged 38, started to menstruate at 14, every twenty-eight days for five days, with severe pain the first two days. She would be bedridden the first day. She weighed 55.4 Kg and was 152 cm tall.

History revealed pneumonia, measles and chickenpox in childhood, and influenza. The patient suffered with brachial and sciatic neuralgia with a change in the weather.

Insulin brand B, 10 units, given during an attack, Sept 6, 1935, relieved the pain in forty-five minutes, and the patient was comfortable for the rest of the day.

CASE 10—Mrs. I. R., aged 24, a secretary, weighed 49 Kg and was 150 cm tall. The menses began at 11 and occurred every twenty-eight days, for six days. Profuse flow with clots occurred on the third and fourth days. Examination was negative.

Oct 9, 1935, insulin, brand B, 10 units, was given for the pain in the abdomen and down the thighs on the first day, with relief in forty minutes.

CASE 11—H. R., aged 27, unmarried, a registered nurse weighing 60 Kg with a height of 157 cm, started to menstruate at 12, every twenty-eight days, for five days. Rectal examination revealed no abnormality.

Oct 7, 1935, for severe, excruciating pain at the onset insulin brand B, 10 units, was given. In thirty-five minutes there was partial relief. In one hour it was complete with a feeling of relaxation. It induced free flow. November 6 menstruation began with severe pain in the abdomen and thighs. Ten units of insulin, brand B, self administered, gave relief in thirty-five minutes.

CASE 12—I. W., aged 26, single, a registered nurse, was 165 cm tall and weighed 58.2 Kg. The menses began at 14 every twenty-nine to thirty days, of four days' duration, with moderate flow. There was severe pain requiring bed rest on the first day.

Physical examination including the rectum, was negative. Blood sugar was 104 mg, and blood urea nitrogen 14.3 mg. Roentgenograms of the chest and the basal metabolic rate were normal.

Insulin, brand C, 8 units, was given for five days before the period. The patient began menstruating Dec 1, 1935 with no pain. For the second period, December 31, insulin, brand C,

8 units, was given daily for four days preceding menstruation, resulting in absolute freedom from pain during the entire period

## COMMENT

Of the twelve cases presented here, insulin was given for from three to seven days before the menstrual period in eight. In seven, with the use of insulin, commercial brands B and C, definite modification and avoidance of pain was effected. With the use of insulin, brand A (second period in cases 7 and 8) there was a delay of three days in the menstrual period in each case, severe headache at the vertex and no relief from pain.

In the four other cases in which insulin, brand B or C, was given during the attack of pain, without previous premenstrual medication complete relief was effected, in each one from thirty minutes to one hour. There was no severe insulin shock in any case, although patient 4 reported sweating when more than 7 units was used. However, she did not follow instructions with regard to the ingestion of orange juice and other carbohydrates.

As was noted by other workers with insulin,<sup>12</sup> not every brand of commercial insulin contains the activating substance necessary to be effective in this condition.

Insulin has been used in gynecology for various hemorrhagic conditions with interesting results.<sup>13</sup> Abel,<sup>14</sup> in experiments on animals, reported a long estrus pause with a decrease in the number of follicles and an increase in the corpora lutea. Poulain-Landrieu<sup>15</sup> mentions the beneficial uses of insulin in the various uterine hemorrhagic conditions and also mentions its use as of value in some cases of dysmenorrhea. Although he does not cite any cases or state the number of patients to whom the treatment was given, he says that it should be tried in every case of functional dysmenorrhea.

In the group of cases here reported most of the patients were underweight and had a lowered basal metabolic rate. None of them showed stigmas of hysteria or psychoneuroses or evidence of other endocrinopathies. The blood sugar levels, when taken, were within normal limits. No severe insulin shock was encountered. With the exception of case 5, there was no pathologic condition of the pelvis noted, and even in this case, with extensive intra-abdominal adhesions and previous salpingo-ovarian disorder, there was entire absence of menstrual pain during the time of insulin administration.

In ten of the twelve cases here reported definite relief was obtained with insulin, either premenstrual, or during the pain. Patient 4 expressed her preference for the premenstrual method of administration because it removed the anticipation of a painful period. On account of her menstrual irregularity and the pressure of institutional work she omitted the daily administration before her last period (December 1935) but gave herself 10 units with the onset of pain. She was completely relieved in twenty minutes.

The use of insulin for dysmenorrhea offers an effective, simple and inexpensive means of relief. If properly used, it is entirely safe. It is too early to say definitely whether it is capable of altering the patient's condition so that after its use for some time there will be permanent absence of pain. The reports of its

success in this group of cases are gratifying. Further metabolic and endocrine studies are in process in some of these patients and will be in others as they present themselves.

## SUMMARY

In a group of twelve patients, all nulliparas, suffering from primary or essential dysmenorrhea ten received practically total relief from menstrual pain by using insulin from three to seven days before or during the period. One patient obtained relief in one period with one type of insulin and no relief during another period with another type of insulin. Another patient was only partially relieved.

## Clinical Notes, Suggestions and New Instruments

## COMA DUE TO BROMIDE INTOXICATION

ERLE B. CRAVEN, JR., M.D. AND FORREST J. LANCASTER,  
M.D. LEXINGTON, N. C.

A white woman, aged 59, had been in a state of alternate coma and delirium for four months. The family history was irrelevant, and except for a chronic or recurring pyelitis there was nothing in the past history that was considered important.

The present illness began insidiously on or near July 20, 1935, and followed a long illness of the patient's daughter. The burden of nursing the daughter had fallen on the patient. The onset was characterized by restlessness, marked emotional instability and disordered, frightening dreams. During the ensuing two weeks these symptoms were intensified, and the patient also complained of blurring of vision and loss of memory. Members of the family noted that there were increasing weakness and ataxia and a growing lethargy. The patient's speech became slurred and her facies vacuous. August 11, approximately three weeks after the onset of the noticeable symptoms, the patient's lethargy had progressed to the point of deep stupor. She lay in this semicomma until November 22, on which day she first showed signs of returning reason. During the period of coma there were frequent outbursts of maniacal excitement, which necessitated restraint. The attacks of mania were apparently reactions to fear-inducing hallucinations. These hallucinations took many forms, but the most frequently recurring were visions of yellow bugs crawling on the bed, policemen threatening the patient with guns and vague, alarming shapes on the walls and ceiling of the room. The patient's diet during the entire period consisted of liquids exclusively, low in quantity and in salt content. The feedings were all forced, the patient taking no food voluntarily. Dextrose solution was given occasionally, both intravenously and by rectum.

On physical examination, November 12, the patient was maximally undernourished and lay in a deep stupor. The temperature was 99 F., the pulse rate 120 and the respiratory rate 18. The latter was not irregular. There were occasional myoclonic movements of the extremities and facial grimaces. The knees were flexed at right angles and in a state of contracture. The skin and mucous membranes were excessively dry, and the tongue was grossly furred. The pupils were pinpoint in size. After dilation with homatropine ophthalmoscopic examination revealed clearly outlined optic disks and normal retinal arteries. There was a pronounced doughlike rigidity of the arms and legs, and the tendon reflexes were markedly hyperactive. The abdominal reflexes were unobtainable. There was no ankle or patellar clonus and the Babinski and Kernig signs were negative.

Examination of the blood showed red blood cells 4,800,000, hemoglobin 94 per cent (Sahli) and white blood cells 7,400 with a normal differential count. The stained smear showed no abnormalities. A voided specimen of urine showed a few white blood cells but no albumin, sugar or casts. Blood urea was 20 mg. per hundred cubic centimeters.

<sup>15</sup> Poulain Landrieu O. Valeur de thérapie de l'insuline dans certaines troubles ovariens. Prog. med. 49: 1940 (Dec. 1), 1934.

The spinal fluid was under normal pressure and reacted normally to jugular compression. It was water clear and contained no excess globulin or cells. The total halides of the spinal fluid were 706 mg per hundred cubic centimeters (120.7 milliequivalents per liter). The spinal fluid bromides were 452 mg (44 milliequivalents per liter) and the chlorides, 449 mg (76.7 milliequivalents per liter). The replacement of halide by bromide amounted to 36.4 per cent. The Wassermann reaction was negative.

November 14, sodium chloride therapy was begun. Twelve grams of salt, in capsules, was given by mouth daily. In addition, physiologic solution of sodium chloride was instilled into the rectum in quantities of 90 cc every four hours. An attempt was made to increase the total fluid intake to 6,000 cc daily. No sedatives or other medicines were given. Five days after the institution of treatment the patient became rational for brief periods, and during these moments she was able to recognize members of her family. Two days later she was rational during most of the daylight hours, but at night the frightening dreams continued to interrupt her sleep. She was excessively weak, and there were tremors about the mouth and eyes and of the hands. Recovery from then on was uneventful, the tremors, weakness and nervousness gradually disappearing. The contractures of the legs were relieved by massage and passive movements.

After complete recovery it was found that the patient's memory had been lost not only for the four months of the acute illness but for a period extending back to July 4, antedating the onset of the delirium by nearly three weeks.

The patient's mentation and behavior were now those of a normal individual, and she was able to give us the history of the early bromide ingestion. For many years she had taken a "patent" bromide preparation<sup>1</sup> during times of emotional or mental distress. During the severe illness of her daughter, with its attendant worry and loss of sleep, she had taken refuge in this preparation more than ordinarily. After the onset of the delirium, bromides were administered in a mistaken, but understandable, effort to control the great restlessness and excitement. A gram of the drug was given from four to six times daily over a long period of time. This, together with the necessity for a liquid diet, naturally poor in salt (which favored the storing rather than the excretion of the offending halide) adequately explains the extraordinary quantity of bromide found in the cerebrospinal fluid.

#### COMMENT

This case is presented because of the several features of unusual interest, namely, the duration of the coma, the complete recovery, and the extremely high bromide content of the cerebrospinal fluid.

As one of us has written in a previous article<sup>2</sup> and as the papers of McFadden,<sup>3</sup> Wile,<sup>4</sup> Harris and Hauser,<sup>5</sup> Diethelm,<sup>6</sup> Wagner and Bunbury,<sup>7</sup> Zondek and Bier<sup>8</sup> and others may attest, the signs and symptoms of bromide poisoning recur with regularity sufficient to constitute a clinical syndrome. Moreover, we believe that cases of profound poisoning are of frequent and widespread occurrence, not only as a result of self medication but as a complication of the treatment of many chronic and acute illnesses. It is important to realize that the induction of bromide delirium is not concerned solely with the ingestion of bromides but is governed also by the factors controlling bromide excretion, namely, the salt and fluid intake. Because of the usual absence of skin rashes<sup>9</sup> and because a history of the ingestion of bromides is often unob-

tainable or unremarked, the etiology of these puzzling comatose and delirious states is but rarely comprehended. The diagnosis should be suggested by the typical signs and symptoms, together with the negative evidences of systemic and cerebral disease.

Given a comatose or delirious patient, lacking the signs, both clinical and chemical, of constitutional disease and in whom the evidences of upper motor neuron damage are conspicuously absent, the diagnosis of bromide intoxication should receive early consideration. Confirmation of the diagnosis is easily and positively made by the quantitative determination of the bromides of the blood or cerebrospinal fluid, or both.

#### SUMMARY

1 In a woman, comatose for four months, the only positive etiologic factor discovered was an extremely high bromide content of the cerebrospinal fluid.

2 Quick recovery from the coma was obtained by the use of measures designed to increase bromide excretion.

3 On the basis of data found in the literature, and from personal experience, it is suggested that there is a typical symptom complex of bromide intoxication which, in suspected cases, gives sufficient warrant for a quantitative determination of the offending halide even in the absence of a history of bromide ingestion.

19 West Third Avenue

#### IMMUNOTRANSFUSION IN UNDULANT FEVER REPORT OF TWO CASES

S. M. CRESWELL, M.D., AND CARL E. WALLACE, B.S.  
TACOMA, WASH.

The more prevalent use of immunotransfusion in the treatment of acute infectious diseases has been confined to the last decade. During this period transfusions of both specific and nonspecific immune blood have been reported with gratifying results. Gordon<sup>1</sup> has shown excellent results in the treatment of severe scarlet fever from the use of specific unaltered immune blood of convalescent patients. Stephenson<sup>2</sup> has reported success from the use of both unaltered and citrated nonspecific blood in the treatment of hemolytic streptococcus septicemia. Other writers have presented equally favorable reports concerning immunotransfusion in various types of septicemia.

Quevli and Nelsen<sup>3</sup> described favorable results following the use of whole unaltered blood transfusions in the treatment of undulant fever. As far as was known, the donors used for these transfusions had never had the disease but the results obtained were attributed to a probable passive immunity of the transfused blood. These physicians stated that in their opinion the ideal donor would be one who had recovered from undulant fever.

In the two cases reported here, an effort was made to discover donors with a high antibacterial immunity. In the selection of these donors, the opsonocytophagic index determination as applied by Huddleson, Johnson and Hamann<sup>4</sup> to Brucella infection was used. Briefly, the method described by Huddleson and his co-workers in determining the degree of immunity to Brucella is as follows:

From a prospective donor, 5 cc of blood is collected in a test tube containing 0.2 cc of a 20 per cent solution of sodium citrate in physiologic solution of sodium chloride. The test should be completed within an hour after withdrawal of the blood. Into a clean glass vial such as that used in the Kahn test are placed 0.1 cc of the whole blood and 0.1 cc of a Brucella suspension from a forty-eight hour liver agar slant. After thorough shaking, the vial is placed in an incubator at

9 In unpublished data from the Duke Hospital in a series of nearly fifty cases of bromide poisoning there were only two cases presenting skin rashes. Both of these were atypical. Craven<sup>2</sup>.

37 C for thirty minutes. It is to be noted that the cells should not be resuspended after the period of incubation. A drop of the sedimented cells is removed by means of a finely drawn capillary pipet and placed at one end of a clean glass slide, then drawn out as in the usual blood smear. To prevent shrinkage of the leukocytes, the film should be dried as rapidly as possible. The slide is then stained with either Hastings or Wright's stain. The ingested *Brucella* organisms are counted in each of twenty-five leukocytes from various sections of the spread.

Chart 1 (case 1) — Temperature during course of illness

Huddleson considers that the absence of ingested bacteria in the cells is indicative of a nonimmune person, that from one to twenty bacteria represents slight immunity, that from twenty one to forty bacteria shows moderate immunity and that more than forty bacteria counted in each cell shows marked immunity. (It is suggested that any one wishing to perform this test refer to Huddleson's original article.)

The donors used in the two cases here reported both showed tests of high immunity. In both instances it was impossible to count the ingested bacteria, owing to the marked piling up of the organisms within the leukocytes.

**CASE 1**—A veterinarian aged 30 a patient of Dr E C Yoder, became ill during the first week in October 1933. He had not had a recent illness but during the three preceding months had tested several herds of cattle for tuberculosis and contagious abortion. Also during this period he had attended a cow that had aborted and was compelled to remove a portion of the placenta which had been retained. About one month prior to his illness some sores developed on his fingers which healed with difficulty.

The illness began with a generalized debility, fever, aching and sweating. These symptoms were followed by moderately severe headaches, chills and weakness. The sweating was particularly profuse at night. October 23 the leukocyte count was 6,400 and the differential count was 54 per cent polymorphonuclears, 40 per cent small lymphocytes and 6 per cent large lymphocytes. The agglutination test for undulant fever was positive in dilutions up to and including 1:160. October 27 the patient's leukocytes showed a very slight ingestion of *Brucella* organisms as indicated by the opsonocytaphagic index test. At this time the agglutination test in the dilution of 1:320 was slightly positive. October 28 the patient was given a transfusion of 500 cc of whole unaltered blood. The donor used was also a veterinarian whose blood possessed high opsonocytaphagic power. Three hours after the transfusion a severe chill developed, followed by high fever. However the patient began to show improvement on the following day and the temperature dropped to normal (chart 1). November 16 nineteen days after the transfusion the agglutination test was positive in dilutions up to and including 1:1280 and the ingestion of *Brucella* organisms in the leukocytes was marked. The patient has shown no recurrent symptoms.

**CASE 2**—A civil engineer aged 44 employed by the city of Tacoma, a patient of Dr H G Willard had had many hours

of overtime work during a period of eight days following a flood directing crews of men in opening up new drainage ditches. Much of the work was in the vicinity of a packing plant. Approximately fifty cattle had drowned in the flood area. During this time the patient became greatly fatigued and stated that he was wet most of the time. Three weeks later he became ill with a severe chill and a temperature of 104 F. After a two days rest he felt much improved and returned to work. Within three or four days he had another chill, followed by fever. He again quickly improved but continued to have repeated attacks at varied intervals.

It was not until March 1, 1934, two months after the initial chill that he was seen by his physician. He complained of a left temporal headache which had been more or less constant but was more severe during the attacks of chills and fever. He complained of pains in the joints, particularly the knees and ankles, with marked sweating requiring a change of bedding three and four times each night. He was drowsy and could not remember incidents of recent date. Weakness was pronounced. By March 5 he was compelled to remain in bed continuously. On this date the leukocyte count was 8,100 with polymorphonuclears 66 per cent, small lymphocytes 28 per cent and large lymphocytes 6 per cent. The Widal test was negative for typhoid para A and para B, in all dilutions. Agglutination for undulant fever was also negative at this time. There were no ova or parasites found in the stools. March 15 an intradermal skin test was made with 0.002 mg of a fat free *Brucella* protein prepared according to the method of Levin.<sup>5</sup> A severe reaction was noted in twenty-four hours.

The injected area was 6 mm in diameter and was swollen and indurated.

March 19 the agglutination test was positive in all dilutions up to and including 1:320, and the leukocytes showed a low opsonocytaphagic power. March 20 the patient was given a transfusion of 500 cc of whole unaltered blood from a donor showing a high opsonocytaphagic index. The temperature dropped in a few hours, as indicated in chart 2. The patient returned to work March 25, five days following the transfusion. At this time the leukocytes showed marked ingestion of *Brucella* bacteria. There has been no recurrence of symptoms.

Chart 2 (case 2) — Temperature during course of illness

#### COMMENT

The therapeutic response with immunotransfusion in the treatment of these cases although there were only two, seems to be sufficiently striking for presentation. The results obtained are attributed to the selection of the proper donor by means of the opsonocytaphagic index test. Whole unaltered blood was preferred in these transfusions in order to prevent any possibility of interference with the immune properties of the donor's blood.

<sup>5</sup> Levin, William. The Intradermal Test as an Aid in the Diagnosis of Undulant Fever. *J. Lab. & Clin. Med.* 16: 275 (Dec.) 1930.

## CONCLUSIONS

1 Immunotransfusion in the treatment of undulant fever was a satisfactory method of treatment in the two cases here reported

2 The opsonocytophagic test is a reliable index in the selection of immune donors

3 The opsonocytophagic index paralleled the clinical condition of these two patients

Medical Arts Building

## UNUSUAL CASE OF BARBITAL POISONING WITH RECOVERY

D. K. CHANG, M.D. AND M. L. TAINTER, M.D.  
SAN FRANCISCO

The clinical fatal dose of barbitol has been stated to be about 10 Gm. The toxic manifestations of overdosage are predominantly depression, with fall of blood pressure, increase or loss of reflexes and reduction in temperature and coma. The following case, from the private practice of one of us (D. K. C.), shows the possibility of recovery from a considerably larger dose, after a protracted period of coma. It illustrates an often overlooked fact that barbitol may sometimes cause a marked febrile response rather than the classic depression of temperature.

L. M. S., a man, aged 22, Chinese, weighing 120 pounds (54 Kg.), being despondent over failure to pass examinations swallowed thirty-six  $7\frac{1}{2}$  grain tablets of sodium barbitol, a total dose of 270 grains (18 Gm.). He was found in deep coma twelve hours later and brought to the hospital. No vomiting had occurred, and the stomach was not evacuated, so the entire dose was retained.

When first seen, the reflexes were very sluggish, and the pupils were contracted and not reactive. Respiration was regular with a rate of 42 per minute; the pulse was 164, and the rectal temperature 102.8 F. During the next two days the temperature progressively increased to a maximum of 107.2 with a pulse rate of 200 and a respiratory rate of 54. At this time the systolic blood pressure was 90 mm. of mercury, the diastolic blood pressure could not be obtained. The temperature, pulse and respiration gradually decreased until the ninth day, when the temperature varied between 100 and 101 F., with a pulse of 95 and respiration of 24 per minute. During this period the lungs were clear. No septic process was detectable to explain the high fever. The urine was heavily loaded with red cells and albumin.

On the fourth day the first evidence of return of consciousness was noted when the patient groaned from the insertion of a needle for hypodermoclysis. On the fifth day the patient began to move his head and open his eyes and the next day was able to talk. On the ninth day a bronchopneumonia developed, which caused a recrudescence of the fever. However, he was sufficiently recovered to be dismissed from the hospital on the thirty-fifth day.

The treatment during the first week consisted chiefly of supportive measures. One liter of 5 per cent dextrose solution was given intravenously, and 2 liters of physiologic sodium chloride solution by hypodermoclysis, each twenty-four hours. Caffeine 0.5 Gm. was injected subcutaneously every four hours and camphor in oil subcutaneously whenever the pulse grew weaker. The extremely high temperature was combated by tepid sponge baths and ice packs. In addition, general nursing care, including frequent catheterization during the first week, was given as needed.

## SUMMARY

A man of 120 pounds (54 Kg.) body weight survived a total dose of 18 Gm. (270 grains) of sodium barbitol, taken with suicidal intent. The poisoning was characterized by a deep coma of six days' duration, a very high temperature and rapid pulse and respiration, in contrast to the usual picture of severe depression of temperature and respiration. Knowledge of the fact that this common depressant may produce stimulant responses in some cases should be of value in diagnosis and treatment of cases of barbitol poisoning.

## USE OF MARINE SPONGE AS PRESSURE DRESSING FOR THYROIDECTOMY WOUNDS

WILLARD BARTLETT, JR., M.D. AND ROBERT W. BARTLETT, M.D.  
ST. LOUIS

We have been so pleased with the result of the use of the marine sponge as a pressure dressing for thyroidectomy wounds that we take this opportunity of calling its advantages to the attention of those doing thyroid surgery. Since the popularization of the marine sponge as a means of applying pressure to skin flaps and to skin grafts by Wilray Blair and others, there must surely have been adaptation of this plan to the treatment of the superficial flaps raised in doing thyroidectomy, but such efforts have not, apparently, been recorded. H. M. Richter tells us of using the common rubber bath sponge, which serve the same purpose and is less expensive.

Personal communication with surgeons doing large numbers of thyroidectomies reveals an incidence of serum collection under the flaps varying from 50 to 90 per cent, the consequence is reflected in a recent publication commenting on an incidence of more than 60 per cent of draining incisions as late as the eighth to the tenth postoperative day. Our experience was formerly somewhat similar, even after abandoning infiltration of the operative field with procaine hydrochloride and developing the plan of cervical nerve block; our incidence of fluid collection was more than 50 per cent. Since we adopted the sponge pressure dressing it has decreased to about 10 per cent.

The sponge should be applied over only a few layers of gauze dressing and covered with only a few more layers of gauze. Adhesive tape, encircling the neck behind, is crossed anteriorly over the sponge. The latter should be reapplied whenever the dressing is changed for forty-eight hours after operation. If skin sutures and drains are removed in twenty-four hours after operation the wound will be found to be cleanly healed by the third or fourth day and no further dressing is necessary, as a rule.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
HOWARD A. CARTER, Secretary

## WESTERN ELECTRIC AUDIPHONE ACCEPTABLE

Manufacturer: Western Electric Company, New York

The Audiphone is an electrically operated, wearable hearing aid. The outfit consists essentially of a microphone, batteries, amplifier, and a bone or air conduction receiver. One type of unit for the less hard of hearing is not equipped with an amplifier.

The receiver employs an armature fixed to the contact surface and a bipolar magnet of high efficiency. As the magnetic field fluctuates with the flow of current through the microphone, the inertia of the magnet causes the receiver to vibrate and the contact surface transmits the vibrations to the bones of the head. The vibrations are picked up directly by the cochlea of the inner ear, thus by-passing certain organs of hearing through which sound normally enters. In cases in which these organs have been impaired by illness or accident, the bone conduction receiver is of particular assistance. In other instances of impaired hearing it has the advantage of leaving the ear open to function together with the receiver. The bone conduction receiver transmits virtually the entire audible range of sound. It fits onto a tiny plug at the end of the transmission cord and can be used interchangeably with the air conduction type of receiver, which is of the conventional type.

The entire receiver weighs slightly over half an ounce and is  $1\frac{1}{16}$  inch wide,  $1\frac{5}{16}$  inches long, and a maximum of  $\frac{9}{16}$  inch deep. The case is made of phenol plastic material.

The power is obtained either from special hearing aid batteries available in four sizes or from three standard flashlight cells, for the latter, a battery case is available but it is not

1 Bartlett Willard and Bartlett Willard Jr. Surg. Gynec. & Obst. 58:737 (April) 1934

part of the standard equipment. The hearing aid batteries, because of their larger size, give longer service per battery unit, but if the flashlight cells are changed when they depreciate below the recommended operating voltage, they are as efficient as the special batteries.

This unit was tested under actual conditions by an investigator selected by the Council, and it was found to be generally satisfactory. When the transmitter is worn under clothing, such as a suit, the firm claims that the loss of amplification amounts to about ten decibels. To obtain the best results, as

is true of all hearing aids, this unit should be worn on the outside of the clothing.

When special hearing aid batteries are sold for hearing units, the Council believes that the battery terminals should be standardized so that a battery, no matter where purchased, will fit all makes of hearing aids. In the case of the Audiphone this has been done, and its battery terminals are those adopted by the Division of Simplified Practices, Department of Commerce, National Bureau of Standards. Furthermore the Council believes that, when these devices are prescribed or sold, the company should permit the patient to try them and be certain that they will fit his specific type of deafness under the particular circumstances in which he is most desirous of aid.

In view of the results of the investigation of this unit, the Council voted to include the Western Electric Audiphone in its list of accepted devices.

Western Electric Audiphone

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

#### SCARLET FEVER STREPTOCOCCUS TOXIN (See New and Nonofficial Remedies 1935 p 391)

United States Standard Products Company, Woodworth, Wis

Scarlet Fever Streptococcus Toxin for Immunization

Prepared by the method of Drs. Dick under U. S. patent 1,547,369 (July 28, 1925, expires 1942) by license of the Scarlet Fever Committee Inc. Marketed in single immunization packages of five vials containing respectively 500, 2,000, 8,000, 25,000, and 80,000 skin test doses of toxin in ten immunization packages of six 10 cc vials containing respectively 500, 2,000, 8,000, 25,000, 80,000, and 80,000 skin test doses of toxin per cubic centimeter.

#### SODIUM CACODYLATE (See New and Nonofficial Remedies 1935, p 88)

The following dosage forms have been accepted

Cheplin's Sodium Cacodylate 0.05 Gm (3/4 grain) 1 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.  
Cheplin's Sodium Cacodylate 0.1 Gm (1 1/2 grains) 1 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.  
Cheplin's Sodium Cacodylate 0.2 Gm (3 grains) 1 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.  
Cheplin's Sodium Cacodylate 0.3 Gm (5 grains) 1 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.  
Cheplin's Sodium Cacodylate 0.5 Gm (7 1/2 grains) 1 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.  
Cheplin's Sodium Cacodylate 1.0 Gm (15 1/4 grains) 2 cc Benzyl alcohol 1 per cent is added for its local anesthetic effect. Prepared by the Cheplin Biological Laboratories Inc. Syracu e N Y.

#### SODIUM CACODYLATE (See New and Nonofficial Remedies, 1935 p 88)

The following dosage form has been accepted

Ampoule Solution Sodium Cacodylate 0.19 Gm (3 grains) 1 cc Prepared by the Lakeside Laboratories Inc. Milwaukee

## Committee on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BRING, Secretary

#### CELLU BRAND VEGETABLE COMBINATION, WATER PACKED

Manufacturer—The Chicago Dietetic Supply House, Inc., Chicago

Description—Canned yellow string beans, asparagus tips, artichoke hearts, okra and pimiento, packed in water without added sugar or salt.

Manufacture—Cellu canned yellow string beans and asparagus tips, artichoke hearts, okra and pimiento are drained, packed in cans in specific proportions, boiling water is added and the cans are sealed and processed for a few minutes, but not long enough to soften, and cooled.

Analysis (submitted by manufacturer)—

	per cent
Moisture	95.6
Total solids	4.4
Ash	0.5
Fat (ether extract)	0.1
Protein (N x 6.25)	1.0
Crude fiber	0.5
Starch (diastase method)	1.8
Carbohydrates other than crude fiber (by difference)	0.5

Calories—0.1 per gram 3 per ounce

Claims of Manufacturer—Packed in water without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

- 1 BONNIE BRAND HAWAIIAN PINEAPPLE CRUSHED, SLICED AND TIDBITS
- 2 BONNIE BRAND HAWAIIAN PINEAPPLE JUICE

Distributor—United Fruit Stores, Inc., Providence R. I.

Packer—Hawaiian Pineapple Co., Ltd., San Francisco

Description—1 Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, p 1106, and April 29, 1933, p 1338).

2 Canned Hawaiian pineapple juice retaining in high degree the vitamin content, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p 1769).

- 1 TRUPAK PREMIUM BAKING CHOCOLATE
- 2 DAVIS BRAND COOKING CHOCOLATE

Distributors—(1) Haas Brothers, San Francisco (2) The Davis Store, Chicago

Packer—Moffat Inc., Boston

Description—Ground cacao nibs or "chocolate liquor" in cake form. Same as Moffat Cooking Chocolate Unsweetened (THE JOURNAL, Jan 20, 1934, p 213).

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standards.

- 1 FORT HAMILTON BRAND TOMATO JUICE
- 2 WHITE BIRCH BRAND TOMATO JUICE

Distributors—1 E. H. Frechtling Company, Hamilton Ohio  
2 Carpenter Cook Company, Menominee, Ishpeming Iron Mountain and Escanaba Mich

Packer—Vincennes Packing Corporation, Vincennes Ind

Description—Pasteurized tomato juice with added salt. Retains in high degree the vitamin content of the raw juice, the same as the accepted Alice of Old Vincennes Tomato Juice (THE JOURNAL Feb 20, 1932, p 640).

## SCIENTIFIC DISCOVERIES AND PATENTS

The problem of medical patents has been agitating the medical profession increasingly in recent years. The "Principles of Medical Ethics" says quite plainly "It is unprofessional to receive remuneration from patents for surgical instruments or medicines, to accept rebates on prescriptions or surgical appliances, or perquisites from attendants who aid in the care of patients."

Through the centuries, medicine has given freely of its discoveries for the benefit of mankind. Vaccination against smallpox, inoculation against hydrophobia, digitalis, and innumerable other methods and medicaments became the property of all who cared to employ them in the control of disease. Now, as medicine has become more complex, involving technical assistants in the fields of biochemistry, physiology, physics and associated branches, great numbers of people who give their full time to the work of the hospital, the laboratory or the care of the sick work with the medical profession but are not bound by the same ethical principles. Moreover, the universities have developed preparations and techniques in their laboratories at considerable expense to the institution, and workers have seen fit to turn over to the universities the control of such products. Thus insulin is controlled by the governors of the University of Toronto, scarlet fever preparations are controlled by the Scarlet Fever Committee Inc., vitamin D preparations by the Wisconsin Alumni Research Foundation of the University of Wisconsin, the Spertt patents by the University of Cincinnati, the Zucker patents by Columbia University, the Doisy patents are controlled by the St. Louis University School of Medicine, and several patents are the property of Stanford University and the University of California.

The American Association for the Advancement of Science published in 1934 a report on this subject with the arguments for and against commercialization of university patents. The problem continues to be studied by the National Research Council and by many other

bodies. The question is one that has concerned the House of Delegates of the American Medical Association, and the Board of Trustees even now is engaged in a survey of the situation.

In the current issue of *Harpers Magazine*, George W. Gray<sup>1</sup> presents an interesting analysis of the present status of affairs as it concerns problems not only in the medical field but in science generally. He points out that separate patent-holding agencies were operating at the beginning of 1936 at the Universities of Cincinnati, Columbia, Cornell, Iowa State College, Lehigh, Pennsylvania State College, Purdue, Rutgers, Utah, Wisconsin, and Wittenberg College. Moreover, the state universities of Illinois and Minnesota, the California and Massachusetts Institutes of Technology, and the Franklin Institute of Philadelphia control either directly or by a committee patents contributed by research workers.

There seem to be three contrasting methods of financial control of university patents: (1) the method of the general holding company, (2) the method of the university holding company, and (3) the direct or committee method. Apparently these methods were established with the chief objective of protecting the public against substitutes and makeshifts. By means of the patent, the inventor can insure that whatever is offered to the public under his invention is technically right.

Mr. Gray feels that, when a new device involves the purity of a process or of ingredients, the public interest is best served by patenting. However, service of the public interest by insuring purity and quality of preparations is far different from commercial exploitation of the fruits of university research.

One of the most cogent arguments now advanced concerns the relationship of a university or research institution to taxation. Endowed universities and research institutions are usually exempt from taxation. They are nonprofit institutions. As an endowed institution, free from taxation, such institutions owe a definite duty to the public, which bears the burden of taxation. This is certainly a practical consideration which may well engage the authorities in the universities responsible for administration of commercially valuable patents.

Again, the exploitation of patents by various universities places them in direct competition with one another, as, for example, the three patents concerned with the development of vitamin D. Under such circumstances the results of current research are jealously guarded and all research probably delayed through failure of research workers to communicate with one another. Indeed, even workers in the same university develop a competitive spirit likely to destroy entirely the type of cooperation in science which is responsible for much of our current progress. The

<sup>1</sup> Gray, G. W. Science and Profits. *Harpers Magazine* 172 (5) (April) 1936.

conception of scientific research is beautifully expressed by Mr. Gray in the following paragraph:

Scientific research, as a recognized full time occupation is one of the youngest of the professions. It has come up out of the basements and garrets of the early experimenters and has attained status among the most honored of the callings of man. Perhaps the laboratory is pressed with economic necessity—but is that warrant for changing its charter? Possibly it can support itself handsomely and independently—but can it survive the shiftings of bases and the readjustments of outlook which commercialization entails? One of its greatest glories is its intellectual integrity and independence—but can this reputation continue unsullied in the clash of competitive sales campaigns of patented commodities, infringement suits and other contentions of the marketplace in which the financial interest of the research institution is on one side of the dispute?

A final consideration concerns the rights of the physician. When our civilization was such as to safeguard the physician considering him as one who gave freely of his knowledge and service to mankind and therefore entitled to special consideration, physicians might well offer freely their time, their service, their original contributions. Our complex civilization of today places ever new burdens on a willing bearer of mankind's tribulations. Surely there was never a problem more complex offered for solution by the best minds of the medical profession.

#### OBITUARIES OF PHYSICIANS PUBLISHED IN 1935

The number of obituaries of physicians published in *THE JOURNAL* during 1935 totaled 3,491. The obituaries of 3,319 physicians of the United States were published as compared with 3,231 in 1934. The total number includes also 172 Canadian physicians, 4 in Hawaii, 2 each in Alaska, France, Philippine Islands and Puerto Rico, and 1 each in Africa, Bermuda, Cuba, England, Germany, India and Switzerland. The obituaries of 83 women physicians were published as compared with 73 in 1934. Graduates of medical schools in the United States for the fiscal year ended June 30, 1935, numbered 5,101. Deducting the number of physicians whose obituaries were published there was a net addition of 1,782 for the year to the ranks of the profession.

*Ages*—The average age at death of those classified as of the United States was 64.2 as compared with 64.3 in 1934. Two physicians lived to be 100 years old and 36 others lived to be 90 or more. Forty-six physicians died between the ages of 25 and 29, 58 between 30 and 34, 74 between 35 and 39, 114 between 40 and 44, 152 between 45 and 49, 254 between 50 and 54, 400 between 55 and 59, 510 between 60 and 64, 499 between 65 and 69, 455 between 70 and 74, 385 between 75 and 79, 225 between 80 and 84, and 109 between 85 and 90. More deaths occurred in January than in any other one month.

*Causes of Death*—Heart disease was again the leading cause of death. Some contributory causes are included in the tribulation, as they have been in former

years. For example, when a report of the cause of death was "chronic nephritis and heart disease," it was published so in *THE JOURNAL* and was recorded on the statistical charts under both diseases. Of the causes of death from heart disease, endocarditis or myocarditis was specified in 355 cases, coronary thrombosis in 220, angina pectoris in 146 and pericarditis in 2. Other diseases of the heart caused 622 deaths. Pneumonia was the second most frequent cause, lobar pneumonia being reported in 270 cases and bronchopneumonia in 90. Cerebral hemorrhage was the third most frequent cause, with 355 deaths, 20 additional deaths were reported as due to paralysis. Fourth on the list was arteriosclerosis with 318 deaths, other diseases of the arteries caused 4. Of 282 deaths reported as due to cancer, the stomach and liver were affected in 56 cases, the intestine in 33, the prostate in 30, in 163 cases the part affected was not specified. Nephritis caused 191 deaths, of which 22 cases were specified as acute nephritis. The number of cases in which embolism or thrombosis, exclusive of coronary thrombosis, was reported was 109, hypertension 84, diabetes and uremia 75 each, diseases of the genito-urinary system exclusive of nephritis, uremia and diseases of the prostate, 56, tuberculosis of the respiratory system 49, other forms of tuberculosis 4, diseases of the prostate 46, cirrhosis of the liver 40, other diseases of the liver 8, ulcer of the stomach 33, appendicitis 29, septicemia 28, influenza 27, senility and pulmonary edema 24 each, paralysis agitans, meningitis and leukemia 19 each, peritonitis 18, cholecystitis and hemorrhage 17 each, intestinal obstruction 16, other diseases of the digestive system 14, gangrene 15, arthritis 12, encephalitis 11, brain tumor 10, pernicious anemia 9, secondary anemia 2, aplastic anemia 1, other diseases of the blood 1, aneurysm and sclerosis 8 each, erysipelas 7, alcoholism, asthma, chronic bronchitis, biliary calculi and cerebromalacia 6 each, abscess, goiter, hemioma and osteomyelitis 5 each, carbuncle, cellulitis, cerebral edema, Hodgkin's disease, mastoiditis, pancreatitis and dementia praecox 4 each, agranulocytic angina, brain abscess, pyemia and streptococcal infection 3 each, acidosis, amebic dysentery, empyema, malnutrition, myelitis, otitis media, peripheral neuritis, pellagra and sinus infection 2 each. Among other causes of death, each given in one case, were acute rheumatic fever, bacillary dysentery, Banti's disease, cerebral infarct, cholangitis, congenital polycystic kidney, diverticulum of the esophagus, diverticulum of the colon, erythema multiforme, encephalomyelitis, epilepsy, Huntington's chorea, heart stroke, Ludwig's angina, morphine poisoning, multiple neuritis, phlebitis, pneumothorax, polythemia vera, purpura haemorrhagica, rattlesnake bite, Raynaud's disease, rupture of the pancreas, ruptured esophageal varices, septic sore throat, syphilis, tetanospasmodia of the spinal cord, tetanus, teratoma of the testicle, tonsillitis, tularemia and undulant fever.

*Accidental Deaths*—One hundred and twenty physicians died as the result of accidents in 1935 compared with 141 in the previous year. Automobile accidents accounted for 71 deaths, 2 more than in 1934. In 1935 deaths from falls numbered 19, burns 6, drowning 5, carbon monoxide poisoning 4, x-ray burns and shooting 3, overdose of medicine 2. One died in the Florida hurricane. One was overcome by gas, 1 was suffocated in a fire, 1 struck by lightning, 1 died of a broken neck from diving into shallow water. In the remaining cases in this group the nature of the accident was not specified.

*Suicides and Homicides*—Suicide was the cause of 47 deaths in 1935, 28 less than in 1934. Shooting accounted for 21 of these deaths, poison for 12, drowning 5, hanging, stabbing and jumping 2 each, incised artery 1, and in the remaining cases the method was not reported. There were 5 homicides.

*Positions*—Among the decedents were 196 who were or had been teachers in medical schools, 407 who served in the World War, 28 veterans of the Civil War, and 45 veterans of the Spanish-American War. One hundred and forty-one had been health officers, 101 members of boards of education, 56 members of boards of health and 24 members of state boards of medical examiners. There were 47 members of state legislatures, 45 mayors, 40 coroners, 25 bank presidents, 15 members of city councils, 14 editors, 10 dentists, 10 police surgeons, 9 missionaries, 7 lawyers, 7 clergymen, 3 postmasters, 2 justices of the peace, and 1 congressman. There were 18 members of the U S Army Medical Corps, 11 of the U S Navy Medical Corps and 11 of the U S Public Health Service.

*Association Officers*—Obituaries of physicians who were or had been officers of the American Medical Association included 2 past presidents, 2 vice presidents, 12 section officers and 2 members of councils. Thirty-two members or former members of the House of Delegates died during the year. Thirty-seven presidents or former presidents and two secretaries of state societies were included among the officials.

### CONTROL OF SYPHILIS AS THE NEXT PUBLIC HEALTH OBJECTIVE

The conquest of syphilis is the next great objective in public health. In spite of the difficulties of compiling statistics on syphilis, sufficient reliable information indicates that it is probably the most prevalent of communicable diseases except for measles in epidemic years. Public health officials have been directing more and more efforts toward the control of syphilis through providing laboratory services for diagnosis, free diagnostic stations and aid through clinics, and free drugs to be used by private physicians in the treatment of the indigent, at least to a noncontagious stage. Recent medical literature has seen the publication of carefully considered studies in standard procedures of treatment.

Four of these cooperative clinical studies<sup>1</sup> which have been printed in *THE JOURNAL* and one taken in part from *Venereal Disease Information*,<sup>2</sup> the monthly bulletin of the United States Public Health Service devoted to this topic, have been combined in a manual of information for physicians.<sup>3</sup>

One of the principal obstacles to the conquest of syphilis has been public squeamishness about facing the problem and the unfortunate classification of syphilis as a venereal disease. It is, of course, a venereal disease only in part. It is principally a communicable disease in the broadest sense. As such it must be handled as other communicable diseases are controlled and discussed with equal frankness. Magazines, newspapers and the radio have been reluctant even to use the word "syphilis." This is a reflection of a popular state of mind which must be altered by educational efforts. There are signs even now of a more liberal attitude. Newspapers are beginning to use the word in headlines, at least a dozen local radio stations of major importance have featured medical broadcasts on the subject,<sup>4</sup> numerous smaller radio stations, especially in New York State, have broadcast transcriptions dealing with syphilis<sup>5</sup> furnished by the health department of the state of New York. When we have placed syphilis in the light we shall have taken the first step toward its conquest.

The history of medical progress shows instance after instance in which the combined forces of medicine and public health have conquered disease as far as public cooperation could be procured. Diphtheria persists only by virtue of incomplete application of preventive measures which have been stressed by physicians and public health workers, smallpox can be extirpated at any time when vaccination becomes universal, typhoid is conquerable by a combination of sanitary engineering and applied immunology whenever these measures are adequately invoked. A greater menace than all of these is syphilis, yet our knowledge is ample for its successful control. With the combined efforts of physicians, public health officials, educators and the public, syphilis can be conquered next.

## Current Comment

### INFECTIOUS ANEMIA OF HORSES

A question has arisen recently as to the possibility of the transmission to man of infectious anemia of horses (swamp fever) by the administration of serums or antitoxins derived from the horse. As far as can be ascertained, transmission to man in this way has not occurred in this country or elsewhere, but two apparently authentic cases have been reported of infection in human beings after direct contact with the disease in horses. Luhrs,<sup>1</sup> a German veterinarian working with infected horses during the war, developed febrile symptoms, diarrhea, pain in the kidneys and signs of anemia. For three years his blood and filtered serum each produced symptoms of infectious anemia on inoculation into horses. Later, Peters<sup>2</sup> described a case of severe anemia (2,000,000 erythrocytes) in a patient after exposure to horses ill with infectious anemia, other symptoms being diarrhea, headache, a herpetiform eruption, occasional elevations of temperature, lumbar pain and general debility. A horse injected with the patient's blood and two horses injected with filtered serum in each case developed symptoms of infectious anemia and died. The disease in horses has a wide geographic distribution throughout the world and has occurred in a number of states in this country. It is insidious in its spread and, especially since horses may carry the virus without obvious symptoms of illness, it is possible that infected animals may gain entrance into establishments producing biologic products for human use, despite precautions that are or could be taken. If human cases presenting suggestive symptoms following the administration of serum or antitoxin are observed, the possibility of infection with the virus of infectious anemia should be considered. Apparently the only satisfactory confirmatory test would be the inoculation of a susceptible horse as was done in the two cases mentioned.

### THE KANSAS CITY SESSION

#### American Branch of International League Against Epilepsy

A dinner meeting to organize the American Branch of the International League Against Epilepsy and to discuss the investigation of epilepsy will be held at the Hotel Muehlebach Tuesday evening, May 12 at 6:30. Those who wish to attend please inform the exhibitor in booth 673 before Tuesday noon.

#### APPLICATIONS FOR GRANTS FROM COMMITTEE ON SCIENTIFIC RESEARCH

The Committee on Scientific Research of the American Medical Association invites applications for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms and further information address the committee at 535 North Dearborn Street, Chicago.

#### DISTINGUISHED GUESTS AT THE KANSAS CITY SESSION

The general scientific meetings at the Kansas City session present this year two distinguished guests from abroad who will no doubt, be greeted with great interest by American physicians. Lord Horder has been physician in ordinary to the prince of Wales, now king of England, since 1923. He is a graduate of the University of London and of St Bar-

LORD HORDER

tholomew's Hospital, consulting physician to the Cancer Hospital, ex-president of the Harveian Society of London, president of the National Birth Control Association and consulting physician to numerous other organizations in both the medical and public welfare fields. He has interested himself particularly in recreation, physical training, eugenics, child guidance, the antinuclear movement and the cremation society. He is known also for his contributions to medical investigation and is the author of *Clinical Pathology in Practice*, *Cerebrospinal Fever*, *Medical Notes*. The *Essentials of Medical Diagnosis* and similar works. He will address the assembly at the annual session in Kansas City on thyrotoxicosis.

Dr Afranio do Amaral of Brazil is head of the Institute at Butantan near São Paulo. Dr Amaral is a graduate of Harvard and has for years been recognized as among the leading authorities in the world on snake poisons and antivenoms. The Antivenom Institute which is a part of the Butantan Institute, is known throughout the world. The institute is equally known

DR AFRANIO DO AMARAL (seated) extracting poison from a rattlesnake

for its investigation in the fields of spotted fever and of Rickettsia. It has charge of the preparation and development of most of the biologic preparations used in Brazil. Dr Amaral will speak at Kansas City on snake poisons. In the illustration he appears on the right extracting the poison from a rattler.

### BROADCASTS FROM THE KANSAS CITY SESSION

Special radio programs will be broadcast from Kansas City during the week of the annual session.

#### NATIONAL BROADCASTING COMPANY

The following programs will be delivered over a network of the National Broadcasting Company:

May 11, 4:30 p. m. Nutrition and the Future of Man by Dr. James S. McLester, President of the American Medical Association. Fifteen minutes.

May 12, 4 p. m. Medicine Marching Forward. The regular dramatized program "Your Health" (originating in Chicago) based on papers or exhibits presented at the convention. Thirty minutes.

May 13, 12 noon. An interview about the Scientific Exhibit with Dr. Morris Fishbein. Fifteen minutes.

#### COLUMBIA BROADCASTING SYSTEM

The following programs will be broadcast over a network of the Columbia Broadcasting System:

May 11, 1:30 p. m. An interview with one or more distinguished foreign visitors by Dr. Morris Fishbein. Subject to be announced. Fifteen minutes.

May 15, 2 p. m. A news broadcast outlining the main events of the convention. Dr. W. W. Bauer. Fifteen minutes.

May 15, 5:45 p. m. Medicine Yesterday and Today. A dramatized program (originating in Chicago) based on papers or exhibits presented at the convention. Thirty minutes.

The hour given is central standard time. Eastern standard time is one hour later, mountain time one hour earlier and Pacific time two hours earlier.

### RADIO BROADCASTS

The American Medical Association broadcasts over WEAF the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met." The title of the program is "Your Health." The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen, your health." The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

**Red Network**—The stations on the Red network of the National Broadcasting Company are WEAF, WEEL, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGI, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAT.

**Pacific Network**—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR.

Network programs are broadcast locally or omitted at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

April 21	Health and the School	Morris Fishbein M.D.
April 28	Infant Care	W. W. Bauer M.D.
May 5	Maternal Care	W. W. Bauer M.D.

### ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

Thirty Second Annual Meeting held in Chicago Feb. 17 and 18, 1935  
(Continued from page 1319)

DR IRVIN D. METZGER, Pittsburgh, in the Chair

### THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 18—MORNING

#### The Federation and the Survey of Medical Schools

DR WILLIAM D. CUTLER, Chicago. I am able to make a partial, incomplete report on some phases of the survey of medical schools that has been going forward now for about a year and a half. The actual visitation of the schools will probably be completed by the first of June. In carrying out this survey, we have relied on two essentially different and yet complementary methods. The first step in our investigation of a medical school is to send forms asking for information regarding the organization and teaching methods and facilities of the different departments of the institution, also for a brief personal history of the members of the faculty who carry on a substantial part of the teaching program. These forms have been filled out by all the schools to which they have been sent and returned to us. However, in spite of our best efforts to make the meaning of these questions clear, some of them are misunderstood, some of them may be slighted, some of them may be inaccurate, and it requires a personal visit to the school and a conversation with the men who have completed the forms to complete and round out the entire picture. We were able to borrow from the University of Syracuse the services of Dr. Weiskotten, who has been dean of that school, professor of pathology there for a long time and is a keen student of medical education. Dr. Weiskotten has made every one of these visits so far. At all times he is accompanied by some one else—a representative of this federation, a representative of the college association, sometimes another member of the Council or some one selected by us to go with him. That gives added importance to the visit, because we are not relying on the observations of a single individual but have in every case the observations of two individuals. The observations made

by these visitors are dictated by Dr Weiskotten every night, and the notes are filed in our office, so that we have a written record, fresh, first hand, to supplement the questionnaire forms which have been submitted as a basis for our permanent and more elaborate study of the schools. So much for the method of the survey.

The first thing that came forcibly to our attention when we began this work was that probably the most important single factor in the character of the work being done in the medical school is the character of the student body. This is along the line of what your president told you last night and what Dr McLester said yesterday afternoon. The most important factor in the quality of the work done by the medical school is the personal qualification, ability, industry, zeal of the medical student himself, so that the most important part of the school lies in the selection of medical students. For ten years there have been more applicants for admission to medical schools than could be received and the schools have been in a position in which they were more or less compelled to make a selection. The evidence that the dean or the admissions committee has on which to make a selection is, of course not as complete as we would like to have it. Unhappily we have not yet discovered any exact means of measuring the personal traits that are all important in determining the success and the usefulness of a physician, but we do have before us the student's academic standing in college, and that serves as one piece of evidence. Lately we have introduced the aptitude test, which brings in another factor in measuring the qualifications of these students. We do not yet know just how much importance we should attach to the aptitude test. Some schools rely a good deal on personal interviews with their candidates. Other schools are less confident. Not all of the schools are dealing with this matter as successfully as we would like. Some of them are a little lax in selecting the last half of their class. Doubtless financial pressure has something to do with it.

I want to make it clear that the Council in undertaking this survey, has not started out with the idea that it was going to reduce the number of medical students. We are not primarily concerned with the number of medical students or the number of men in the medical profession. Our job is to formulate standards of medical education, and if the formulation and enforcement of proper standards should reduce the number of medical students, it must be accepted as an inevitable consequence, just as it was twenty-five years ago. On the other hand if the formulation of proper standards should lead to an increase in the number of medical students that again is not our concern. We are concerned with the formulation and application of proper standards of selection and proper methods of teaching.

During recent years, probably owing to the period of depression, a good many schools have allowed themselves to yield to the demands of this increasing number of applicants and to take in larger numbers of students than they have been able to care for properly. In some cases their laboratories are overcrowded. In some cases they have to run two or three successive sections multiplying the teaching load of their instructional staff. Most of the schools in which this condition has been found have expressed their readiness to cooperate with us by reducing the size of their student body. But please get it in your minds that the purpose of this survey is not the reduction of students but the preparation of better trained and better qualified physicians.

Another feature that stands out in our survey so far is that the teaching of the clinical subjects has not advanced as satisfactorily as the teaching of the laboratory subjects. We have found that the older, purely didactic methods of teaching by lectures or large clinical demonstrations have persisted to an extent that is not in conformity with the best methods of teaching at the present day. We believe that the only way one can teach a man to examine a patient is by having him examine the patient. The actual teaching, the backbone of the teaching of medicine, surgery, obstetrics and pediatrics must be through personal application by the student to the examination of the patient of the methods that he has been taught under close supervision, so that his work is immediately checked and corrected and so that he learns each day to do the work better and better. That kind of teaching takes time. It takes an abundance of clinical material. One of the weaknesses that

has been generally manifested has been the failure to develop that kind of teaching. This is manifested in an important way in obstetrics. Ever since the Council formulated its first standards for medical schools, it has specified that each student should personally conduct a number of labor cases under supervision. We find that that standard is being honored in the breach more than in the observance. There is some difference of opinion. There are those who believe that obstetrics has become a specialty comparable with eye, ear, nose and throat work, with major surgical work and that the graduate in medicine even after the completion of an intern year, ought not to be expected to do obstetrics and therefore they make the subject elective. This is a question of social philosophy. If the philosophy that has prevailed up to the present time is correct, we have got to ask some of these schools to be a little bit more particular in carrying out this particular requirement.

There is one other feature. A medical school cannot be run without money, and especially during these hard times, some of the schools have been severely pressed. Some of them have had to cut salaries. They have had to diminish the size of their staff. We feel that those cuts should be made in other divisions of the school. I believe we are justified in asking these schools whatever else they may do not to cut down on anything that has to do with the training of physicians.

### The Two Year Medical School

DR G. M. WILLIAMSON, Grand Forks, N. D. Twenty-five or thirty years ago these groups meeting today favored the idea of two year medical schools. The incomplete schools were not only welcomed but enjoyed high rating from the start and with minor exceptions they have held that rating until this time. It seems to me that fair and unbiased recognition should be given to any incomplete school that is doing satisfactory work. The chief argument against the two year schools at this time seems to be that they are unable to make the necessary correlation between the laboratory and the clinical work and that newer and better ideas of medical education do not approve of the handling of courses considered good practice some twenty-five years ago. Probably the best correlation of all is done by the wise teacher and has little or no relation to elaborate provision or organization. I am sure that it is the experience both of students who began their training in the incomplete schools and of the schools themselves that transfer students are in general at no disadvantage whatever. It is the experience of North Dakota students and of the clinical schools to which they have gone that they find no difficulties in making adjustments. It is sometimes questioned whether students who complete two years of work in an incomplete school are able to transfer or find opportunities to continue their studies. It is of course true that the continuation of any two year school depends not only on its being able to give satisfactory instruction but on the ability of complete schools to accept its students. It is the experience of the school in my state, and I think this is typical that no student who should at all be encouraged to go on has failed to find an opportunity to do so. The two year schools are small schools or should be. Their students finishing in medicine are a little more likely to go into general practice and into the more rural parts of the country than are students that come from the more congested centers. These schools are in a favorable position to know of aptitudes, attitudes and other elements of personality and character that should be taken into consideration in selecting students. The intimate contacts of teacher and student operate to many advantages. The fact that a transfer must be made in order to complete the training is at once a challenge to good work felt by both instructor and student. Only one student who has finished the curriculum at the University of North Dakota with the graduation average has so far failed to find an opportunity to go on. Of forty-five students that transferred to Rush in the few years just preceding 1934 twenty-two had made slightly higher average grades than they had made here nine had exactly the same averages and fourteen had dropped slightly. Of thirty-nine North Dakota students transferred to Northwestern from 1927 to 1934 one died and thirty-eight have graduated there or are in the present graduating class. Of the thirty-eight three finished or graduated there in the upper one tenth of their respective classes, thirteen in the upper one fourth and twenty-eight, or nearly

75 per cent, in the upper one half. The six students who transferred to Pennsylvania from 1923 to 1933 made the second highest group average in the work of the third and fourth years. (The highest group average was made by the students transferring from Utah, the second by those from North Dakota, the third by those from other complete or four year schools, the fourth by the large group of Pennsylvania's own students.) After completing two years of medical training, students in acceptable schools are eligible to write on part 1 of the National Board examination. Thirty-eight have passed in all subjects at once, eight have made partial failures, but most of these have rewritten the subjects in which they were low and received the certificate later in accordance with the rules of the National Board, four have failed. It seems to me that the University of North Dakota School of Medicine, and the same is true for the other two year schools, is needed for several reasons. In this argument for continuation of the two year school in the Middle West, I believe that the Council directing medical education should seriously consider conditions existing in sparsely populated parts of our country. A careful survey of medical education should include not only all the schools that have to do with regular medicine but all schools or efforts of any kind that pretend to train men for any form of the so-called healing arts. If it is deemed necessary to limit or to reduce the number of men entering the profession a better way for all concerned than to eliminate the two year schools or to make unreasonable demands on them would seem to be to prorate the number of admissions each school should accept, or to advance the requirements for entrance or both. In prorating or limiting admissions consideration should of course be given to both the facilities of a school and its location and the reasonable service that it might be expected to perform for either a limited or a wider territory. If requirements are to be increased, it would seem that the added requirements should be in the way of quality of the work done rather than in any total or specific quantity.

DR BENJAMIN J. LAWRENCE, Raleigh, N. C. I believe and most of the influential physicians in my state believe that there is a definite place in American medical education for the two year medical schools. I believe that the presence of the two year medical schools is sound in theory and in practice. The medical course today and as administered throughout this country is long and arduous. Most boys graduate from college young and it is a decided advantage to many of these youths if they can remain at their original college of liberal arts or at their own university for an additional two years, during which time their characters become more mature and better rounded. They are closer home in many instances. There is another important phase to be mentioned. In these two year medical schools the student comes in contact with the faculty in a close relationship. The influence of the professor plays an important part in shaping the lives and future of these young men entering the medical profession. This is not feasible in the great universities. What a blow to our profession it would have been had we not had on the lives of their students the influence of such men as Gross, the elder, Da Costa, D. Hayes Agnew, Joseph Leidy, Marion Sims, Murphy and Nicholas Senn. Medical schools were relatively small when these men were developing. The teachers in the two year schools in North Carolina have played a tremendous part in shaping the destiny of the profession in our state. Such is not the case in an overcrowded school of several thousand students. Many of the finest doctors the world has produced came from humble parentage. These stalwart individuals fought their way up and obtained admission into a medical school. The people of my state feel that the medical course is long enough and that it is already too expensive. It taxes the physical strength and frequently exhausts the financial ability of the student and of his family. Had it not been for the two year medical schools in North Carolina many of the leading doctors in North Carolina would never have had the opportunity to enter on their career. We beg of you to allow these two year schools to remain for the benefit of the people in the rural districts who need their product and for the benefit of the student who is most worthy in every particular and yet whose financial condition is very limited. These boys enter the junior classes of the best four year medical schools in the world. They stand shoulder to shoulder with the men who took their first two

years at the great four year medical schools. They are not inferior in character or in scholastic standing and they make as good doctors as ever practiced. The medical profession needs the two year schools because it needs the fine type of manhood grown under rugged circumstances. Society needs the two year medical schools. Doctors are concentrating in large cities, but in many instances the rural districts are actually in need of doctors. My state is a rural state. We have had our two year schools for thirty years or more. Of more than 2,000 doctors in North Carolina, about 1,600 active today, nearly all took their training at one of the two schools which now offer just two years in medicine. A ruling that would seriously handicap these institutions would arouse organized medicine in our state. We have demonstrated for half a century that we can control the supply of doctors in North Carolina and we believe in keeping the standard high.

## DISCUSSION

DR EDWARD A. KNOWLTON, Holyoke, Mass. I should like to ask the speakers whether there is any great percentage of students in these two year schools who have been refused admission to the four year schools. I ask that with the idea that the number of applicants to the larger schools exceeds those they take in, ten to one. I wondered whether there were many going to the two year schools who have previously been refused admission to the larger four year schools.

DR H. E. FRENCH, Grand Forks, N. D. I think probably I can answer that. We have a great many applications from the class you speak of. We do not take them. Our students are practically all from our own state. We probably have some from some western state where there are no medical schools.

DR KNOWLTON. I wanted to find out whether many of these two year students had already applied for admission to a four year school and been refused admission.

DR THOMAS J. CROWE, Dallas, Texas. After hearing the young man from North Carolina, it seems to me that he is justified in everything he said with reference to the first two years in medicine, unless pathology and technical subjects are carried over into the third and fourth year. I find that the universities are not giving the men enough fundamentals in the first two years. I am speaking now of the academic institutions.

DR ERWIN SCHFAK, Des Moines, Iowa. There is such a thing as unfitting a doctor for certain types of practice. He can be kept in college so long in clinical work so long in laboratories so long and in hospitals so long that he will not go into the rural areas. Even in Iowa there are rural districts that are insufficiently supplied with medical talent. I think they have a peculiar condition of their own, and I do not think that any group should arbitrarily determine what they are to have and what they are not to have. I do wonder, however, what preliminary qualifications they expect. Nobody has discussed that.

DR E. H. KLOMAN, Baltimore. I am not especially interested in any of the two year schools, but my belief is that they have a much better selection of students than the big colleges have. Secondly, I think the personal touch which they have is much greater and they turn out men who have been in personal touch with the teachers to a much greater extent than in the larger schools.

DR FRANK M. FULLER, Keokuk, Iowa. In our observations of progress in medical education, we do not give proper consideration to past development. I was connected with a school which went out of existence. That school was established in Iowa the first school ever established west of the Mississippi River in 1849. That school went on successfully to 1908 and then it could not meet the demands of medical education and it merged with Drake University. Then, because the city of Des Moines could not handle the job, it merged into the great University of Iowa College of Medicine. In 1927, nineteen years after the Keokuk Medical College closed its doors there was a gathering of some of the graduates of that school at Iowa City. I said to those men, 'Why do you want to come back twenty-five years after your alma mater has closed its doors?' They told me over and over again, 'We want to come back because we appreciate the personal effort that the faculty

of Keokuk Medical College made to start us" These small schools have a place That school provided the great western growing country with excellent, capable, competent men, who have risen to high places in the profession These two year schools may be doing the same thing today

DR GEORGE M WILLIAMSON, Grand Forks, N D I want to correct my friend from Iowa In a school established in North Dakota thirty years ago a requirement for admission was two years of college work I doubt that you had that in your schools in Iowa at that time

DR BENJAMIN J LAWRENCE, Raleigh, N C That reminds me that the distinguished John Farrell, who is now with the Rockefeller Institute, came from one of these small and insignificant schools

### Comments on National Board Examinations

DR J STEWART ROYMAN and EVERETT S ELWOOD Philadelphia The National Board of Medical Examiners has just completed its second decade The fifteen original members laid the foundations of this undertaking with care They sought and secured the approval of the House of Delegates of the American Medical Association The Secretaries of War, the Navy and the Treasury authorized their respective surgeon generals to participate in the board's activities The Federation of State Medical Boards endorsed the plan, and its leaders gave freely of advice and valuable assistance The deans of the medical colleges and many of their department heads contributed the scientific guidance which determined the nature and scope of the examinations Exchange visits by committees of the examining boards of England and Scotland and of the National Board of Medical Examiners were made, with the result that the young board in this country had the great benefit of the advice and experience of these distinguished overseas boards which have been conducting national medical examinations for a century and a half

Four of the organizations mentioned—the Council, the federation, the Association of American Medical Colleges and the federal services—have from two to six representatives each in the membership of the National Board Medical training has undergone changes and an elevation of standards during the past twenty years These have made it possible for a comprehensive medical examination on a nation-wide basis to be of service to medical education in ways not contemplated when the National Board was organized Some of the medical colleges in this country introduced the comprehensive examination and its use in this field has been growing Perhaps owing in part to its newness and in part to lack of a full understanding of its purpose, this type of examination has in some instances failed to be a real test of the student's mastery of a major division of medical study A satisfactory definition of the comprehensive final examination as given by Prof Edward S Jones of the University of Buffalo is "an examination of a college student covering subject-matter greater in scope than a single course" The examinations of the National Board of Medical Examiners and those of the state medical examining boards are referred to by Dr Jones as final comprehensive examinations He demonstrates conclusively however, that a real comprehensive examination must be more than a factual test of memorized details The National Board is earnestly striving to give a broad comprehensive examination Many of its questions begin with the word discuss It is an examination by outside examiners, all of whom are prominent members of the faculties of medical schools

In addition to the written examinations part I and part II, the three day practical and clinical oral examinations, part III, affords an opportunity to try out the young physician in action Here he is given patients to study and laboratory problems to solve which are similar to those he will meet in actual practice In the division of clinical medicine of part III, for example, he studies the patients assigned to him takes a history of the so called long case and makes his diagnosis and prognosis Then two examiners—one asking questions the other appraising the answers—thoroughly discuss the case with the candidate not only as to his conclusions but also as to the reasons for these and his estimate of the various factors involved A distinct effort is made to clinicalize the examinations so far as possible Even the examinations in physiology

biochemistry and pharmacology are conducted at the bedside when suitable cases are available

The six main divisions of part III are subdivided, and the grade in a main division is made up of the grades attained in its subdivisions A candidate passes this part if the average of his grades in the main divisions is 75 per cent or more Recently the board has adopted the rule that grades below 60 per cent in any of the subdivisions are not acceptable if the grade for the corresponding main division is under 75 per cent In such cases the candidate is "referred" in this subdivision and required after a three months interval to pass a reexamination This regulation is proving satisfactory The National Board examinations the board believes might properly be called a barometer of medical education When a representative number of students from any one school pass the National Board's examinations year after year with a degree of success higher than the average for the whole group taking the examination, it is fair to conclude that such results indicate that these students have received a medical training equal to the best given in this country today

A number of medical schools are making a study of the results which their students attain in the National Board's examinations The printed reports of the examinations which carry the individual records by identification numbers only, are sent to schools that so request The identification numbers of the students at the schools receiving the report are checked to indicate which were their students in the examination The reports enable them to determine how the students at their school passed in comparison with the group as a whole It also enables them to determine how their students handle each subject in the examination in comparison with the group as a whole and in comparison with the success of their students in other subjects of the National Board's examinations Should the grades in any one subject fall very high or very low in comparison with the grades made by the same students in other subjects, it is apparent that either the examination in this subject or the teaching was not in line with the examinations and the teaching in other subjects The board recognizes the great responsibility that this use of its examination places on those charged with their direct conduct Five schools are now requiring their students to take and pass either part I of the National Board's examinations or both parts I and II Several other schools have given their students the option of taking the National Board's examinations or the school's comprehensive examination In one or two schools, passing the National Board's examinations in part I excuses the candidate from a portion of the final comprehensive examination given at the end of the fourth year The three organizations now conducting the survey of medical schools, namely the Council on Medical Education and Hospitals, the Association of American Medical Colleges and the Federation of State Medical Boards all have representative members on the National Board of Medical Examiners As to the future we wish to say that in the improvement and the conduct of its examinations the board must depend largely as it has in the past, on the medical colleges and the hundreds of their faculty members who are so generously assisting in its part III clinical examinations in the twenty-two established centers throughout the United States

### Final Objective

DR HAROLD RAPINS ALBANY, N Y It has been eight years since I first suggested the proper subdivision of functions among the various interested bodies, and six years since the responsibility of the supervision of medical education was placed in the hands of the Association of American Medical Colleges The results have been disappointing The association has failed to provide the funds and the administrative machinery necessary for the inspection and supervision of medical schools throughout the country Largely as a result of this failure and in view of the long period that had elapsed since any thoroughgoing inspection of our medical schools had occurred the Council on Medical Education and Hospitals during the past two years has undertaken a complete reinspection of all the medical schools of this country and Canada This has been done with the cooperation of the Association of American Medical Colleges and the federation but the terms of this cooperation have been indefinite and confusing In my opinion unless the final results of this survey have the support

of the Council the association and the federation, acting as a joint cooperating body, its effectiveness will be diminished. On the other hand, there is no gainsaying the fact that a great deal of good has already been accomplished by the survey. A large number of schools have definitely recognized their weak spots and have taken steps to remedy them.

The survey has spelled the end of any form of medical sectarianism in our schools. The problem of the two year schools is at last receiving the serious consideration which it deserves. Not least of the accomplishments has been the definite limitation in the number of students admitted as freshmen in various medical schools. The need for regular, complete reinspections at not too infrequent intervals has been demonstrated. One of the objectives considered by this survey has been the approximate number of physicians who should be trained each year and the capacity of our medical schools to train a definite number.

It should not be overlooked that as far as the protection of the public health is concerned the control of medical education and licensure is ineffective unless at the same time there is adequate machinery for the elimination of unlicensed practitioners and the discipline of licensed physicians. Possibly the greatest stimulation to the solution of these problems has been this annual congress, in which the interested bodies have freely exchanged ideas. It is probable that a permanent organization made up of representatives of these various bodies or at least a permanent consulting committee of representatives of these bodies might make more effective the achievement of the final objective.

#### DISCUSSION

DR JOHN H. J. UPHAM, Columbus, Ohio. The discussion of the two year school has been thoroughly carried out so that I will restrict my remarks largely to the inspection of medical colleges going on at present and the final objective. I think we all feel a deep sense of appreciation to the American Medical Association and to the Council for undertaking this very arduous work. To me, the great question is: What are we going to do about it? For over thirty years I have been connected with a medical college starting in a very humble capacity and working up in the last ten years to an administrative position. Almost as long as I have been in practice I have been interested in organized medicine and I am extremely anxious that the position of the American Medical Association should be thoroughly understood. For twenty-three years I have been a member of a state medical board. I can look at these things, therefore, from three different angles. It seems to me that we have a sort of military body, that the Council of the Association might be compared to the general staff, the Association of American Medical Colleges might be compared to the commissary or the quartermaster's department, and the members of the state medical boards are the men in the field and really in the front-line trenches protecting the people from unqualified practitioners. Recently I took occasion to analyze the character of the membership of the state medical boards. Without counting those few states that have duplicate boards of different schools, there are practically 314 members on the forty-eight state boards and the board of the District of Columbia. Of the 300 professional members of the boards, 119 are listed in the American Medical Directory as general practitioners. 160 of them are listed as specialists with a strong leaning toward surgeons. Twenty-one are listed as teachers, having some connection with a medical college. Such a group of men cannot give to other people, to any other group, the actual duty of police power. That group should not be allowed to assume the onus of responsibility and criticism which would undoubtedly arise from some quarters. The only solution it seems to me is that this federation of boards should work out a method of active cooperation that will be for the best interests of the public which we serve. To my mind the best solution of that sort would be as Dr Rypins suggested a representative body that shall combine the interests of all three of the organizations that are interested in this subject, that we should have a representation from the Council but the work of the Council is really fact finding. The Council should report to this body composed further of representation from the Association of American Medical Colleges and a goodly representation from the Federation of State Medical Boards. The members of this body could then work out a plan from their own needs

in their respective localities, from their interest in the fact that they must bear the responsibility of licensing and, therefore, guaranteeing to the people of their own state the quality of the candidates who come to them for examination. I think this body could go further. The present curriculum is in a very unsatisfactory state. As administrator I am constantly under pressure from all sides, specialists demanding more time for their respective specialties. We are trying to crowd the whole field of medical science into four years of instruction. Our students are dissatisfied, this can be seen from the fact that more and more of them are taking two years, three years and four years of postgraduate instruction in connection with hospital service. I feel that an organization of bodies such as I have mentioned could work out a curriculum that would be for the production of what Dr Bierring spoke of yesterday, the basic doctor. Perhaps we might then work out a plan for the legalization finally of the various specialties. But our present curriculum must be cut down in unessentials in order that we can give our graduates, really, a basic foundation for the practice of medicine.

DR WILLARD C. RAPPLEYE, New York. It seems to me that the inspection of the medical schools is putting the emphasis where it belongs, namely, on the quality of the educational process in these various institutions. I am sure, as I see the group working, that it is quite solicitous for these so-called two year schools, which might more appropriately be known as partial medical schools, as they are for the four year schools. After all, the basis on which the approval of any individual school ought to be made is the quality of the instruction in that institution. What was emphasized this morning also is extremely important, namely, that the unit of education is after all, the student and since it is not a matter of subject or of credits but of the character, the industry, the personality and the other qualifications of the individual student, that is the crux of all education. The second thing that this survey is bringing out is the fact that the medical course as such is a unit and that we are not so much concerned with the individual subjects of a curriculum. After all, what we are concerned with in the federation more particularly perhaps than even the individual schools is the end product, namely, a qualified man to go into the practice of medicine with safety. Perhaps we have seen in the setting up of this survey or reclassification of the medical schools one more historical step being taken in the direction of an ultimate plan of licensure in this country which began in 1904 with the setting up of the Council and other studies that have been made, namely, that we are ultimately going to come to licensure on the basis of training and not on examination. Roger II of Italy was perhaps the man who first formulated that, 700 years ago, and that has been recognized all over Europe as the basis for licensure, namely, an adequate training in a recognized institution. It is my hunch that we shall undoubtedly see licensure in this country on the basis of training rather than examination. Dr Upham elucidated the idea of a better correlation between these various agencies. I think that at the moment we are entering into another period of confusion unless we get some better coordination and integration of these various activities. One cannot help but be struck by the situation in this country, the similarity between it and that which existed in Great Britain just prior to the establishment of the General Medical Council in 1858. In educational matters we in this country are fifty or sixty years behind the older countries of Europe. I think that we are approaching a period when we are going to come to the establishment of some kind of a council which will coordinate the problems of medical education, of medical licensure in a way that is satisfactory to the profession, to the universities and to the licensing bodies. That was one of the conclusions reached by the Commission on Medical Education, whose report was issued in 1932. Of course nothing has yet come of it but I think it is likely to develop just as there has been now rapidly developing a recognition of our responsibility in regard to the registration of specialists.

DR JAMES N. BAKER, Montgomery, Ala. The appeal of the National Board to me has been rather strong. I had the feeling that, since there remain only five states that do not give recognition to the diplomates of the National Board, we might interest ourselves in trying to get a full hundred per cent of our membership giving such recognition. It would be a stim-

lus to the medical schools to have their faculties sufficiently interested to try to have their students appear before the National Board. Many of these young men develop sort of an inferiority complex regarding their ability to match up to the test of the National Board. I think that would be helpful in eliminating such an inferiority complex. Licensing boards might think of the recent diplomate of the National Board in the light of the individual that they are examining rather than through reciprocity or individual endorsement. His expense in taking the National Board examination is around \$100. Then when he comes to locate in a state through reciprocity or individual endorsement, he is viewed not in the light of one to be examined by that board but in the light of reciprocity and there, again, he is taxed. I think we might give consideration to viewing diplomates of the National Board in that light rather than in the light of reciprocity and making them pay the reciprocity fee.

DR THOMAS J CROWE, Dallas, Texas. If the classification of medical colleges shall be put out jointly by the federation and by the Council on Medical Education and Hospitals and, if possible, by the National Board of Medical Examiners we can go into the courthouse and the legislature and defend it. But we cannot go into either place and defend it in my state if the classification is made by one single organization the American Medical Association. It will be a great lever in the hands of the prosecutor of medical violations if we can go in with that backing, in other words if the boards of medical examiners of the United States are the legal and authoritative body. I should say the federation should head the list. I want to say a word on the National Board. It is now in my opinion the highest medical credential in the world and I am strongly for it, and I hope some day I shall be able to tell you that Texas has adopted it.

DR WILLIAM R. DAVIDSON, Evansville, Ind. I would like to support Dr. Crowe in what he says about that matter of classification. The reason the Indiana board came here as a body was that very thing. We had a recent case in which a lawyer expected to go into court regarding the classification of the medical school. His contention was based on the fact that the board had not inspected it for several years and it might have improved. To get around that our whole board came up to pass on that inspection, do it ourselves, not accept the American Medical Association's classification or the Council on Medical Education and Hospitals' classification because as he said, that had no legal standing that was up to the board to determine. This federation is the only legal body entitled to issue licenses, and the more it can be brought into our own fold, I think the stronger we shall be in court.

DR J. EARL MCINTYRE, Lansing, Mich. I wish to commend Dr. Davidson and Dr. Crowe for their remarks because Michigan is in the same boat. Our attorney general's department has repeatedly ruled that we cannot accept the classification of an individual, nonofficial group such as the Council on Medical Education and Hospitals of the American Medical Association. Therefore we feel that this is a step in the right direction.

DR IRVIN D. METZGER, Pittsburgh. That was foreseen when our part of the work was authorized. It does give legal value to it and it can be used in the states in prosecutions to much better advantage than it could be if it were from an unauthorized or unauthorized body alone.

DR D. C. PATTERSON, Bridgeport, Conn. There was one point with regard to the two year medical schools and other schools. There is greatly emphasized the lack of clinical material. I do not see any reason why these men in the second year class should have to see sick people. They should be made to study normal healthy individuals thoroughly and there is no lack of material of that nature for them to study.

DR HAROLD RYANS, Albany, N. Y. I am delighted at the reaction of the representatives of the various boards with reference to the official status of the federation regarding the report of these inspections. I would therefore move that the secretary of the federation be instructed to advise the Council on Medical Education and Hospitals as to the attitude of the Federation of State Medical Boards with reference to the procedure to be followed in announcing the results of the inspection.

[The question was called for, put to a vote and carried.]

(To be continued)

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF INTEREST OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ALABAMA

**Bill Passed**—S. 89 to amend the law authorizing nonprofit corporations to operate hospital service plans, has passed the senate. Among other things, this bill proposes to eliminate the prohibition in the present law against furnishing to the purchaser of a certificate for group hospitalization any benefits and privileges named in his certificate until a period of sixty days after the purchase date has elapsed. The bill also proposes certain changes with respect to the reserve such corporations must maintain.

### ARIZONA

**State Medical Meeting at Nogales**—The Arizona State Medical Association will convene in annual session in Nogales, April 23-25, with headquarters at the Hotel Montezuma under the presidency of Dr. Charles R. K. Swetnam, Prescott. Wednesday evening, April 22, a public meeting on cancer will be held. Speakers will be Drs. Orville N. Meland, Los Angeles; Roderick D. Kennedy, Globe; Clarence E. Young, Prescott; Charles S. Kibler, Tucson, and E. Payne Palmer, Phoenix. Guest speakers on the scientific program will include the following physicians:

Fred D. Vickers, Deming, N. M., Leukemia with Report of a Case of Fifteen Years Standing.  
Jefferson R. Lemmon, Amarillo, Texas, Problem and Management of the Crying Child.  
James W. Hendrick, Amarillo, Surgical Management of Duodenal Ulcer.  
Robert C. Martin, San Francisco, New Developments in Pathology and Treatment of the Ear.  
Isaac H. Jones, Los Angeles, The Prescribing of Hearing Aids.  
Rea E. Ashley, San Francisco, Prevention of Sinus Disease.  
George N. Hosford, San Francisco, and Roderic P. O'Connor, San Francisco, O'Connor Operation for Heterophoria and Heterotropia.  
Earl D. McBride, Oklahoma City, Surgical Treatment of Arthritic Joints.  
George D. Mahon, Dallas, Texas, Complications Seen in Thyroid Disease.  
Frederick C. Cordes, San Francisco, Ocular Changes Resulting from Syphilis of the Central Nervous System and the Administration of Trypanamide.  
Harold F. Whalman, Los Angeles, Dinitrophenol Cataract.  
Richard O. Schofield, Boulder City, Nev., Fractures of the Os Calcis.

The governor, Dr. Benjamin B. Moeur, will address the Saturday morning session on 'The State, the Industrial Commission and the Medical Profession'. There will be two symposiums, one on tuberculosis, the other on medicine. Memorial services for the deceased members will also be held.

### ARKANSAS

**State Medical Meeting at Hot Springs**—The sixty-first annual session of the Arkansas Medical Society will be held at Hot Springs National Park, April 27-29, with headquarters at the Arhington Hotel and under the presidency of Dr. Melvin E. McCaskill, Little Rock. Speakers will include the following physicians:

Roscoe G. Leland, Chicago, Changes Confronting Modern Medicine.  
William D. Haggard, Nashville, Fundamentals of Gutter Surgery.  
J. Arthur Myers, Minneapolis, Using Our New Knowledge of Tuberculosis in Childhood.  
James J. Waring, Denver, Importance of Physical Examination in the Diagnosis of Pulmonary Disease.  
Horion R. Casparis, Nashville, Tenn., Feeding the Sick Infant.  
Edward Lee Dorsett, St. Louis, Internal Podalic Version.  
Meyer Wiener, St. Louis, Detachment of the Retina.  
Willis C. Campbell, Memphis, Physiologic Principles Applied to the Treatment of Fractures.

Monday evening, April 27, a public meeting will be addressed among others by Dr. Leland and Dr. Haggard on State Managed Medicine and What Price Health respectively. A memorial session will be held Tuesday. Arkansas physicians included on the general program are:

Je. e. D. Riley, State Sanatorium, Some Practical Thoughts and Suggestions to the General Practitioner on Tuberculosis.  
Forrest A. Corn, Jr., Lonoke, Diphtheria.  
Martin C. Hawkins, Jr., Searcy, Retroverted Uterus: What to Do About It.  
Delmas K. Kitchen, El Dorado, Postpartum Atony of the Uterus.  
Herbert Moulton, Fort Smith, Glaucoma.  
Frank Vinson, Little Rock, Vienna a Few Years Ago. A Medical Center.

Virgil L. Payne Pine Bluff, Results with Ionization Treatment in Nasal Allergy  
 Theron E. Fuller Texarkana, Blastomycosis of the Larynx Complicating Carcinoma  
 James A. Foltz Fort Smith The Rising Mortality in Appendicitis  
 Berry L. Moore El Dorado High Carbohydrate Diet in Diabetes  
 Darmon A. Rhinehart Little Rock X-Ray Treatment of Acute Infections  
 Francis J. Scully Hot Springs National Park Tonsillitis and Hyperthyroidism  
 Maurice F. Lautman Hot Springs National Park The Sedimentation Test in Chronic Arthritis Its Value as an Aid to Differential Diagnosis and Treatment  
 Robert A. Milliken Little Rock Low Back Pain  
 Joseph F. Shuffield Little Rock The Human Foot  
 Francis Walter Carruthers Little Rock Common Foot Complaints  
 Sam Phillips Little Rock Cyanosis in Infancy  
 Donald Smith Hope Agnesia of Abdominal Muscles in New Born Infant  
 Alan G. Cazort Little Rock Present Status of Vaccine and Serum Therapy

The program of one session Wednesday will be given by members of the staff of the Army and Navy General Hospital. Capt. Albert H. Robinson, "Chaulmoogra Oil in Treatment of Arthritis." Major William J. Carroll "Roentgenologic Aspects of Thoracic Tumors," and Major Chancey E. Dovel, "Treatment of Chronic Empyema." The Arkansas State Pediatric Association will hold its second annual meeting at the Arlington, April 27. Speakers will include Drs. Casparis on tuberculosis, Robert A. Strong, New Orleans, "Care of the New-Born for the First Ten Days," and E. C. Mitchell, Memphis, immunization problems. The woman's auxiliary to the state medical association will also be in session, April 27-29.

### CALIFORNIA

**Prevalence of Influenza**—The bulletin of the state department of health reports that about 12,000 cases of influenza were recorded in California during February. In some places school attendance was only 75 per cent of normal. A representative of the Rockefeller Institute for Medical Research, New York, made special studies, particularly in the San Joaquin Valley and the San Francisco Bay region obtaining material for laboratory studies now in progress at the institute. The epidemic was prevalent during the latter part of January and all of February, with the peak occurring at the end of January or during the first part of February.

**State Association News**—The supreme court refused March 29, to hear the appeal of the supervisors of Kern County who had been enjoined from admitting pay and part pay patients to county hospitals. This action sustains the injunction of the circuit court which was recently upheld by the court of appeals. Plans for the organization of a subsidiary corporation for malpractice insurance and indemnification or for group insurance with existing companies were reported on by a special committee at the council meeting April 10. A survey of tax supported county hospitals is being made by an association committee. Abuses will be demonstrated, administration policies advanced and the amount of free services rendered by physicians computed.

### FLORIDA

**State Meeting Aboard the S S Florida**—The sixty-third annual meeting of the Florida Medical Association will be held on the S S Florida April 27-29 on a cruise to Havana, under the presidency of Dr. Herbert L. Bryans, Pensacola. In Havana, entertainment has been planned including golf at the Havana Country Club and sightseeing trips. The scientific program will be presented by the following physicians:

Louis M. Orr Orlando Present Day Conceptions of the Management of Prostatic Obstruction  
 John C. Vinson Tampa Cautery in Acute Epididymitis and Orchitis  
 Louie M. Limbaugh Jacksonville Collapse Therapy of Pulmonary Tuberculosis  
 Kenneth A. Morris Jacksonville Surgical Treatment of Pulmonary Tuberculosis  
 Hubbard H. Gates Bradenton Sulphur the Forgotten Remedy  
 Ralph E. Russell Ocala Treatment of Eye Diseases by the General Practitioner  
 William C. Roberts Panama City Progress Toward Lessening Maternal Morbidity and Mortality  
 Paul B. Welch Miami Management of Peptic Ulcer  
 Samuel Marion Salley Miami The Systolic Murmur Its Interpretation  
 Joseph W. Taylor Tampa Role of Sinusitis in the Production of Cough  
 Harry Hamilton Cooke Miami Trigeminal Neuralgia  
 James G. Lively Jacksonville Brain Surgery and Epilepsy  
 Prescott LeBretton St. Petersburg The Value of Skeletal Traction Especially in Fractures About Joints

The seventeenth annual meeting of the Florida Railway Surgeons Association will also be held on this trip convening Monday morning. The first annual meeting of the Florida

Pediatric Society will be held Monday morning in the smoking room of the S S Florida. Speakers will include the following physicians:

Arthur H. Weiland Coral Gables Orthopedic Surgery in Childhood  
 William W. Anderson Atlanta Ga. Relationship of General Medicine to Pediatrics  
 Walter C. Jones Jr. Miami Relationship of General Surgery to Pediatrics  
 Thomas E. Buckman Jacksonville Blood Dyscrasias in Infancy and Childhood  
 Gilbert S. Osincup Orlando Respiratory Infections in Infancy and Childhood  
 William W. McKibben Miami Diseases of the New Born

The fifth annual meeting of the Florida Radiological Society will be held at the McAllister Hotel, Miami, April 26.

### ILLINOIS

**Tuberculosis Meeting**—The twenty-seventh annual meeting of the Illinois Tuberculosis Association was held at the Orlando Hotel, Decatur, April 6-7. Dr. William A. Hudson, chief, division of thoracic surgery, Grace Hospital, Detroit, conducted a clinic on intrapleural pneumolysis. The speakers on the program included:

Dr. David O. N. Lindberg Decatur Role of the Chest Roentgenogram in Tuberculosis  
 Dr. Robinson Bosworth Rockford Essential Considerations Affecting the Selection of Patients Who May Profit Most from Sanatorium Treatment and Primary Reasons for Eliminating Certain Groups from the Sanatorium  
 Dr. Arthur S. Webb, Wheaton, Basic Elements in Sanatorium Treatment  
 Dr. Herbert L. Pettitt Morrison Problems Facing the Physician Treating Tuberculosis in the Home  
 Dr. Irenaeus L. Foulton East St. Louis A Practical Approach to the Tuberculosis Problem in the Large Counties of Southern Illinois Which Have a Large Negro Population

At the annual banquet Tuesday evening, Dr. Gerald B. Webb, Colorado Springs, gave "An Outline of the History of Tuberculosis."

### Chicago

**The Pasteur Lecture**—Charles Judson Herrick, Sc.D., professor emeritus of neurology, University of Chicago will deliver the fourteenth Pasteur Lecture of the Institute of Medicine of Chicago Friday evening, April 24, in Thorne Hall on McKinlock Campus, Northwestern University. His subject will be "Neurobiological Foundations of Modern Humanism."

**Gehrmann Lectures**—Dr. Victor G. Heiser, formerly director of Far East for the International Health Board, Rockefeller Foundation will deliver the Gehrmann Lectures for 1935-1936 in the Medical and Dental Laboratory Building, 1853 West Polk Street April 29-30 and May 1. The titles of the lectures are "Coordination of Disease Control Throughout the World by the League of Nations," "International Research in Leprosy" and "Dietary Opportunities in Preventive Surgery."

**Department of Psychiatry Expanded**—As a part of the general reorganization of the department of psychiatry at Michael Reese Hospital, Dr. Martha Goldinger Wilson MacDonald has been appointed in charge of child psychiatry and Dr. Milton L. Miller, resident psychiatrist in charge of the inpatient service. Dr. MacDonald is a graduate of the University of Pittsburgh School of Medicine and has been associated with the Danvers State Hospital, Danvers, Mass., the Illinois Institute of Juvenile Research and the Payne-Whitney Psychiatric Clinic, New York. Dr. Miller graduated from Harvard Medical School. He served on the staff of the Enoch Sheppard-Pratt Hospital in Baltimore and, under a fellowship of the Rockefeller Foundation, studied one year at Queen Square Hospital, London, and one year at the Payne-Whitney Psychiatric Clinic, New York. Dr. Jacob Kasanin, formerly clinical director of Rhode Island State Hospital for Mental Diseases, Howard, R. I., was recently appointed director.

### IOWA

**Prevalence of Smallpox**—The state department of health announces that twenty-seven cases of smallpox were reported during the week ended March 21. Reported cases of this disease for the first three weeks of March are more than five times the number reported a year ago, and thus far in 1935 the number of reported cases of smallpox is over six times that for the same period in 1935.

**State Medical Meeting in Des Moines**—The eighty-fifth annual meeting of the Iowa State Medical Society will be held in Des Moines, April 29, 30 and May 1, with headquarters at the Hotel Savery and under the presidency of Dr. Thomas A. Burcham. A symposium on intracranial lesions will be held Wednesday morning with the following speakers:

Drs William E Ash, Council Bluffs, Olan R Hyndman, Iowa City, John D Camp, Rochester, Minn., and Cecil S O'Brien, Iowa City Thursday morning the program will be presented by the following physicians

Solon Marx White Minneapolis Essential Hypertension  
William Wayne Babcock Philadelphia Breast Tumors  
Arthur C Christie Washington D C, Modern Conception of Irradiation Therapy in Malignancy  
Samuel J Kopetsky New York Diseases of the Petrous Portion of the Temporal Bone from the Standpoint of the General Medical Man the Neurologist and the Otologist  
Philip C Jeans Iowa City Feeding Cases

Wednesday and Thursday afternoons will be devoted to sectional conferences, with Friday morning set apart for papers by the following

Dr Bahcock Anesthesia  
Dr White Paroxysmal Cardiology  
Dr Christie Medical Economics  
Dr Olin West Chicago Secretary and General Manager American Medical Association Medical Organization

The "medical minstrels of 1936" will present The Social Security Act" at the smoker Wednesday evening The annual banquet will be held Thursday evening with Dr James C Hill, Newton, as toastmaster Dr Burcham and Dr Prince E Sawyer, Sioux City, will deliver their addresses as president and president-elect of the society, respectively Most Rev Gerald T Bergan, bishop of Des Moines will also speak The State Society of Iowa Medical Women will hold its thirtieth annual meeting April 29, speakers will include Dr Florence Brown Sherbon Lawrence, Kan on 'The Woman Physician in a Changing World' The woman's auxiliary of the state society has also planned an elaborate program for its annual session at this time

## LOUISIANA

Health at New Orleans—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended April 4, indicate that the highest mortality rate (26.8) appears for New Orleans and the rate for the group of cities as a whole 13 The mortality rate for New Orleans for the corresponding period last year was 15.5 and for the group of cities 12 The annual rate for eighty-six cities for the fourteen weeks of 1935 was 13.7 as against a rate of 12.7 for the corresponding period last year Caution should be used in the interpretation of these weekly figures, as they fluctuate widely The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate

## MAINE

Pneumococcus Typing Stations Established—Seventeen stations for typing pneumococcus sputum have been established in Maine by the state bureau of health Persons unable to pay may obtain Felton's refined concentrated serum free at the station if the sputum appears to be positive for type I or type II pneumonia Persons able to pay may also purchase the serum from the typing station if their drug stores do not have a supply on hand or are unable to get a supply promptly Following a study by the bureau of health on the value of typing and treatment, a fund was granted by the governor and his executive council to institute this service

## MINNESOTA

Society News—At a meeting of the Hennepin County Medical Society April 8 in Minneapolis, Drs James S Reynolds and William P Sadler Jr, spoke The society was addressed April 1 by Drs Walter H Fink and Miland E Knapp—The Minneapolis Surgical Society was addressed April 2 by Drs Richard R Cranmer on 'Bilateral Transplantation of the Ureters into the Sigmoid for Exstrophy of the Bladder,' and Alfred W Adson, Rochester, 'Essential Hypertension—The Rationale of Surgical Treatment by Extensive Sympathectomy'

Hospital Conference—The thirteenth annual conference of the Minnesota Hospital Association will be held at the Hotel Lowry, St Paul, May 14-15 Speakers will include Drs Herbert A Burns, Ah Gwah-Ching, on 'The Control of Tuberculosis Among Nurses and Hospital Personnel,' Seymour R Lee, superintendent, Ancker Hospital, St Paul Relationship of the State Hospitals to the Private Hospitals' William H Hengstler, St Paul 'Medicolegal Aspects of Keeping Hospital Records' and George A Earl, St Paul Nursing Education from the Medical Point of View

## MISSOURI

Diphtheria Immunization Campaign—A campaign to immunize children against diphtheria will be conducted in Kansas City, April 20-25 This week has been set aside for attention to families of low income The health department will furnish alum precipitate toxoid without charge and asks that it be administered for a charge of not more than one dollar In cases in which this fee cannot be paid free immunization will be given at the Kansas City General Hospital From 1920 to 1923, when there were no immunizations, 723 cases of diphtheria were reported with an average of 56.5 deaths During 1934-1935 6,068 immunizations were carried out, 121 cases of diphtheria were reported with nine deaths

## NEW YORK

Medical Museum in Rochester—A medical unit in the Rochester Museum of Arts and Sciences is to be established under the auspices of the Rochester Academy of Medicine The new section will be operated as a teaching museum accessible to all citizens who have a legitimate interest in the historical, artistic or scientific aspects of medicine, according to the *New York State Journal of Medicine* Permanent exhibits will be built up but there will also be special and rotating exhibits on timely subjects

State Medical Meeting—The one hundred and thirtieth annual meeting of the Medical Society of the State of New York will be held at the Waldorf-Astoria, New York, April 27-29 The house of delegates will meet Monday, April 27 general sessions will be held Tuesday and Wednesday afternoons and section meetings Tuesday and Wednesday mornings Speakers at the general sessions will be

Lord Horder chief of medical service St Bartholomew's Hospital London

Dr James S McLester Birmingham Ala President American Medical Association Influence of the Present Day Depression on the Nutritive State of the American People

Dr William M James Panama R P Epidemiology Diagnosis and Treatment of Anemias

Dr Harrison S Martland Newark N J Teaching of Forensic Medicine

Dr Walter M Simpson Dayton Ohio Artificial Fever Therapy of Syphilis and Gonococcal Infections

Dr Urban Maes New Orleans The Place of Surgery in Treatment of Peptic Ulcer

Dr Fred W Rankin Lexington Ky Malignant Neoplasms of the Colon

Dr William G Exton New York Differential Diagnosis of Conditions Associated with Sugar Excretion

There will be symposiums on the nervous system in relation to automobile and industrial accidents arthritis, diseases of the liver gallbladder and pancreas, silicosis, industrial diseases and accidents to the hand Invited guests to address the sections include

Dr Walter Bauer Boston Classification and Differential Diagnosis of Joint Diseases

Dr Dean D Lewis Baltimore Surgical Lesions of the Pancreas

Dr Geza de Takats Chicago Surgical Aspects of Acute Peripheral Vascular Disease

Dr Harry Hudnall Ware Jr Richmond Va Full Term Extra Uterine Pregnancy

Dr Leonard G Rowntree Philadelphia Role of the Thymus Gland in Growth and Development

Dr Sanford R Gifford Chicago Ocular Therapeutics

Dr Nolan D C Lewis Washington D C Extraneural Pathology of Paranoia and Manic Depressive Psychoses

Dr Charles C Higgins Cleveland Factors Influencing the Formation and Dissolution of Renal Calculi and Their Application to the Prevention of Recurrent Renal Lithiasis

Dr David M Davis Philadelphia Rationale of Treatment in Urinary Infection

Dr Harry Hauser Cleveland (with Dr George T Pick New York) Roentgen Diagnosis of Malignant Tumors of the Stomach

Dr Thomas P Sprunt Baltimore Certain Aspects of Blood Flow

An open forum will be held Wednesday evening, April 29 in the ballroom of the Waldorf-Astoria at which the following speakers will discuss 'What the Community Should Know about the following subjects

Dr Albert A Epstein New York Diabetes

Dr George P Muller Philadelphia Appendicitis

Dr James S Greene New York Stuttering and Stammering

Dr Arthur J Bedell Albany Failing Eyesight

Dr Charles Gordon Heyd New York Gout

Dr Louis C Schroeder New York Infantile Paralysis

Dr A Raymond Dochez New York Common Colds

Dr Morris Fishbein Chicago Quacks and Quackery

At the annual banquet Tuesday evening guests of honor will be Lord Horder of London, Dr Willard C Rappleye dean Columbia University College of Physicians and Surgeons and William M Lewis LL D, president, Lafayette College Easton Pa These guests will speak and Dr Frederic E Sondern, retiring president of the society, will also make an address

## New York City

**Diploma Lost**—Dr David Hershkowitz has reported the loss of his diploma from the New York Homeopathic Medical College. He was graduated in 1921.

**Alumni Day at Long Island College**—The annual meeting of the Alumni Association of Long Island College of Medicine will be held at the college April 25. At a morning session Dr Adolph G De Sanctis, a graduate of 1914, will present a paper on "Appendicitis in Childhood," which will be discussed by Drs Thomas M Brennan and Carl Laws. At luncheon Dr William E Lippold, 1905, will be the speaker. The annual dinner will be held at the Knights of Columbus Club, Prospect Park West.

**Society News**—At a meeting of the Medical Society of the County of New York, March 23, speakers were Drs Lucy DuBois Porter Sutton, on "Diagnosis of Chorea and Its Relation to Rheumatic Fever", Irving R Roth, "Certain Aspects of Recurrent Affections in Juvenile Rheumatism," and Valentina P Wasson, "An Attempt at Immunization of Rheumatic Fever Children"—Dr Eugene R Marzullo and Frederick B Flinn, Ph.D. addressed the Medical Society of the County of Kings, March 17, on "Lead Poisoning" and "Arsenical Poisoning in the Industrial Field" respectively.—Dr Walter T Dannreuther gave an afternoon lecture before the Medical Society of the County of Queens, March 20, on "Clinical Manifestations of Extra-Uterine Pregnancy."

## NORTH CAROLINA

**The Negative Wins State Medicine Debate**—Negative teams were generally victorious in debates held throughout North Carolina March 27 on the question Resolved, That the several states should enact legislation providing for a system of complete medical service available to all citizens at public expense, the *Raleigh News and Observer* reported March 28. According to this report, coaches and judges expressed the opinion that the question was "unusually one-sided."

## OHIO

**Typhoid Epidemic at Mansfield**—More than 100 cases of typhoid had been reported up to March 27 in an outbreak at Mansfield. At that time the source of infection had not been determined, more than 170 tests having been made of the city water without evidence of contamination. About 7,000 persons in the town had been immunized. The health officer, Dr Willard C Hanson, issued a warning against capsules that were being sold for immunization instead of inoculation, newspapers reported. Chlorination of the entire city water supply was begun March 20, only one section of the city previously had chlorinated water. Representatives of the state board of health were reported to have gone to the city March 23 to assist in the investigation.

**Alumni Meeting at Kansas City**—Medical alumni of Ohio State University will have a dinner meeting Wednesday evening, May 13, in Kansas City, during the annual session of the American Medical Association. The place will be announced later. Dr John H J Upham, Columbus, dean of the medical school, and Dr Jonathan Forman, Columbus, secretary of the medical alumni association will be present. John B Fullen, national alumni secretary, will also attend and will exhibit motion pictures of the university's 1935 football season. Those who plan to attend should notify Dr Arthur L Osborn, 600 Professional Building, Kansas City, Mo, who is in charge of local arrangements. Dr Henry W Lehrer, Sandusky, is president of the medical alumni.

## PENNSYLVANIA

**Society News**—Dr Zoe Allison Johnston, Pittsburgh, addressed the Fayette County Medical Society Uniontown, April 2 on "Indications for Use of Radium and X-Rays in the Treatment of Malignancy."

**Auxiliary Sponsors Lectures**—The Woman's Auxiliary of the Schuylkill County Medical Society conducted its first health institute April 14 in Pottsville. Speakers included Dr James Stratton Carpenter, Pottsville, on antepartum and maternal welfare. Harry Logan, D.D.S., Mt Carmel, facial deformities. Edwin B Twitmyer, Ph.D. professor of child psychology, University of Pennsylvania Philadelphia, freedom and discipline as factors in mental hygiene, Dr John A Sweeney, Philadelphia, tuberculosis, and Dr Peter B Mulligan Ashland, control of cancer. Mrs W Burrill Odenatt, Philadelphia state president of the auxiliary, was also a speaker.

## Philadelphia

**Orchestra Organized**—The Philadelphia County Medical Society Orchestra held its first rehearsal, March 6, under the direction of Mr Gordon Kahn, about forty musicians attended.

**Group Medical Service Ruled Illegal**—The state insurance commissioner has ruled that the organization headed by Dr Charles Dudley Saul, furnishing medical service to subscribers at \$2 a month, constitutes an insurance business. In order to continue, the commissioner said Dr Saul must organize an insurance company and modify his contracts to conform with insurance laws.

**Personal**—Dr Charles E G Shannon was elected president of the Alumni Association of the Jefferson Medical College, January 15.—George D Rosengarten, Ph.D., member of the Committee of Revision of the U S Pharmacopeia and former president of the American Chemical Society, died at his home in Philadelphia, February 24, aged 67. Dr Rosengarten was vice president of the Powers-Weightman, Rosengarten Company for many years, retiring when that firm merged with Merck and Company in 1927.—The staff of Memorial Hospital gave a reception, March 17, in honor of Dr James W McConnell, recently appointed professor of neurology at Temple University School of Medicine.

**Society News**—Dr Roger C Graves, Boston, among others addressed the Philadelphia Urological Society, March 23 on "Bladder Complications of Carcinoma of the Cervix"—The annual conversational lecture of the Pathological Society of Philadelphia was delivered at a joint meeting of the society and the Philadelphia Roentgen Ray Society, April 2, by Dr Antoine Lacassagne, assistant director of the Radium Institute, University of Paris, his subject was "A Hormonal Pathogenesis of Adenocarcinoma of the Breast"—Drs Orthello R Langworthy, Baltimore, and Harold G Wolff, New York, addressed the Philadelphia Neurological Society, March 27, on "A Clinical Study of the Control of the Bladder by the Central Nervous System" and "The Site of Action of Acetylcholine and Its Biologic Significance" respectively.—A symposium on arthritis was presented at the meeting of the Philadelphia County Medical Society April 8, by Drs Theodore F Bach, John Eiman, Charles W Scull and Ralph Pemberton.—Dr James B Murphy, New York, delivered the fifteenth Nathan Lewis Hatfield Lecture before the College of Physicians of Philadelphia, April 1, on "Etiology of Cancer Based on Present Knowledge."

## RHODE ISLAND

**Bills Introduced**—S 212 and H 857, to amend the workmen's compensation act, propose to raise to \$150 the liability of an employer for medical services, exclusive of hospital services, furnished a workman injured in the cause of his employment, and to raise the employer's liability to \$200 for medical services rendered to an employee who has received hospital treatment for more than fourteen days. The bills also propose to make certain enumerated occupational diseases compensable.

## SOUTH CAROLINA

**Bill Enacted**—S 1119 has been enacted, authorizing the city council of any municipal corporation of more than 2,000 and less than 10,000 inhabitants, which has acquired, constructed or caused to be constructed a hospital, to establish a city hospital commission to operate and manage the hospital.

**Bill Passed**—H 2050 has passed the house, proposing to create a health board of Charleston County, to consist of five members, four to be appointed by a majority of the Charleston County legislative delegation and one to be appointed by the city council of Charleston. The county health board is to be authorized to employ a county health officer for Charleston County, who is to employ, with the approval of the county health board, a chief sanitary inspector, sanitary inspectors and a county health nurse. The county health board is to be empowered to make reasonable rules and regulations for the promotion of health and the prevention of disease within the county.

## SOUTH DAKOTA

**Combined Meeting of Related Professions**—Six inter-related medical groups in South Dakota will hold their annual meetings in Sioux Falls during the week of May 4. This plan is the result of efforts of the medical economics committee of the South Dakota State Medical Association to develop interest in problems common to the professions and to effect organization of an interprofessional council. Each group appointed two

members to this council and all selected the same meeting place and time. Meetings will be conducted separately, except on Wednesday, May 6, when a combined meeting will be held with a program dealing with economic matters followed by a banquet in the evening. The organizations are in addition to the state medical association, the South Dakota State Dental Association, South Dakota State Veterinarians' Association, South Dakota State Nurses' Association, South Dakota State Hospital Association and South Dakota State Pharmaceutical Association.

### WISCONSIN

**Radio Station to Refuse "Patent Medicine" Advertising**—It is reported that, as a result of efforts of the Woman's Auxiliary of the Medical Society of Milwaukee County, Station WEMP, Milwaukee, has informed the society that objectionable products such as "patent medicines" will not be advertised over that station.

**Society News**—Speakers at a meeting of the Milwaukee Society of Clinical Surgery, March 24 were Drs Lewis J Pollock, Chicago, on "Diagnosis of Peripheral Nerve Injuries," Theodore H Burbach, Milwaukee, "Rectal Surgery," Loyal Davis, Chicago, "Surgical Treatment of Epileptiform Seizures," and Ernest V Smith, Fond du Lac, "Removal of a Large Dermoid Cyst from the Anterior Mediastinum." Among speakers at the winter meeting of the Ninth Councilor District Medical Society at Marshfield, February 20 were Drs Arthur J Patek, Milwaukee, on "Coronary Disease," Harry Culver, Chicago, "Borderline Problems in Diagnostic Urology," and Rudolph W Roethke, Milwaukee, "Toxemia of Pregnancy." Dr Oliver P Kimball, Cleveland addressed the Medical Society of Milwaukee County March 13, on "Twenty Years of Goiter Prevention" and Dr Arnold S Jackson, Madison chairman of the special committee on goiter, State Medical Society of Wisconsin, on "The State Program as It Relates to Goiter Prevention." Dr William Walter Wasson, Denver addressed the Milwaukee Roentgen Ray Society February 15, on "Differential Diagnosis Between Pulmonary Tuberculosis and Nontuberculous Disease of the Lungs."

### GENERAL

**Examinations in Urology**—The American Board of Urology, Inc., announces that examinations for its certificate will be held in Boston, May 22-24. Examinations will also be held in Kansas City, Mo., May 8-10, preceding the meeting of the American Medical Association.

**News of Meningitis Epidemics**—Public gatherings were forbidden in Covington, Ky., by an order of the city board of health March 25 after three cases of meningitis had appeared in Kenton County. Pike County in eastern Kentucky was placed under a ban March 21, when three new cases appeared in Pikeville, making the total in the county eight. The state board of health reported that 182 cases had been reported in the present outbreak, most of them in the southeastern counties. There have been about fifty deaths.—Two deaths from meningitis have been reported among 1280 soldiers from the transport ship *Republic* now under quarantine at Fort Clayton, Canal Zone, according to newspaper accounts March 29.—A Civilian Conservation Corps camp at Tampa, Fla., was placed under quarantine March 18, when a member of the corps was found to have meningitis.—A Negro high school in East St. Louis, Ill., was ordered closed March 21 after the death of a student from meningitis; three other recent deaths were believed to have resulted from the disease.

**Medical Bills in Congress**—*Change in Status* H R 8874 has been reported to the House providing that for the purposes of promotion there shall be credited to officers of the Medical Corps all active service as officers of the Medical Reserve Corps rendered by them between April 23 1908 and April 6 1917. *Bills Introduced* H Res 481 introduced by Representative Daly, Pennsylvania, proposes to request the Administrator of Veterans' Affairs to submit a report to the House of Representatives respecting the naval hospital at Philadelphia, setting forth the facilities at the hospital the extent of its use by veterans the needs for additional facilities for veterans at the hospital the number of veterans who applied for hospitalization during the past year and certain other facts. A similar resolution H Res 432 proposing to request the Secretary of the Navy and the Administrator of Veterans' Affairs to submit the report was reported to the House by the Committee on Naval Affairs with recommendation that the resolution not pass. H J Res 561 introduced by Representative Mapes, Michigan and referred to the Committee on Rules proposes to create a Committee on the Reorganization of the Executive Branch of the Government to consist of

fifteen members five to be appointed by the President of the United States, five Senators to be appointed by the President of the Senate, and five members of the House of Representatives to be appointed by the Speaker of the House. H R 12169, introduced by Representative Hoepfel, California, proposes to increase the pensions payable to totally disabled veterans of the Spanish-American War the Philippine Insurrection and the China relief expedition. H R 12172, introduced by Representative Risk, Rhode Island proposes to authorize an appropriation of \$1200,000 to erect in Rhode Island, a veterans hospital for the diagnosis care and treatment of general medical and surgical disabilities.

### CANADA

**Balfour Lecture**—Dr Melvin S Henderson, professor of orthopedic surgery, Mayo Foundation, Rochester, Minn., delivered the tenth annual Donald C Balfour Lectureship in Surgery at the University of Toronto April 6. Dr Henderson's subject was "Orthopedic Surgery: A Historical Review."

**Health Insurance Bill Passed**—The legislature of British Columbia passed a health insurance bill April 1 by a vote of 29 to 14. Employees will pay 2 per cent of their wages but not more than 70 cents per week. Employers will pay 1 per cent but not more than 35 cents per week of the employees' wages. The government will contribute \$50,000 to set up an organization under which the scheme will be operated, a commission to be composed of a chairman, a vice chairman and two or three members. Their maximum remuneration will be respectively \$7,500, \$6,000 and \$2,500 a year. The commission will be assisted by a technical advisory board of six members including the provincial health officer, the chairman of the workmen's compensation board, one physician, a representative of a women's organization and two others whom it may be deemed advisable to appoint.

## Government Services

### Dr Parran Named Surgeon General

Dr Thomas H Parran, Jr. since 1930 health commissioner of the state of New York, was appointed surgeon general of the U S Public Health Service March 27. Dr Parran was nominated for the position March 23 and was sworn into office April 6. He succeeds Dr Hugh S. Cumming who retired February 1 after sixteen years service. Dr Parran is 43 years of age. He graduated from Georgetown University School of Medicine in 1915. He was commissioned as assistant surgeon in the U S Public Health Service in 1917. He became medical officer in charge of the Muscle Shoals Sanitary District and chief medical officer at the government nitrate plant in 1918. He was appointed executive officer of the medical department of the War Risk Insurance Bureau in 1919 and in November of that year was placed in charge of the Tri State Sanitary District comprising the lead and zinc mining areas of Kansas, Missouri and Oklahoma. From 1921 to 1923 he served as state director of rural sanitation in Missouri and subsequently was assigned to the Illinois State Department of Health as director of county health work. In September 1926 he was appointed assistant surgeon general and given administrative charge of all venereal disease control activities of the U S Public Health Service. Dr Parran is president elect of the American Public Health Association. In 1935 he was chairman of the American delegation to the International Congress of Dermatology and Syphilis in Budapest. He is the sixth surgeon general of the U S Public Health Service and the first who has served as state health officer prior to becoming surgeon general.

### CORRECTIONS

**Northwoods Sanatorium**—In the *Tuberculosis* Number of THE JOURNAL Dec 7 1935 page 1905 it should have been indicated that Northwoods Sanatorium at Saranac Lake, N. Y. is fully equipped for roentgenographic, fluoroscopic and pathological laboratory services.

**Typhoid Transmission by Rectum**—THE JOURNAL April 4 page 1224 in a Query and Minor Note indicated that there did not appear to be any record of transmission of typhoid by way of the rectum through the use of rectal tubes contaminated with typhoid bacilli. More recently a reference has been found to a series of cases reported by Dr C R Herve of Oswego, N. Y. in the *American Journal of Public Health* of February 1929, page 166.

#### Bill to Restrict the Advertisement of Nostrums and Appliances

A bill to check the glaring evil of the more or less fraudulent widely advertised nostrums and surgical appliances has received a first reading in the house of commons. The bill has received the support of the British Medical Association, the Society of Health Officers, the Pharmaceutical Society, newspaper and advertising associations and bodies representing the drug trade, and the manufacturers of surgical instruments. The bill makes it illegal to hold out as effective any medicine or appliance for the cure or prevention of Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxia, lupus or paralysis, also for the cure of amenorrhea, hernia, blindness, any structural or organic ailment of the auditory system habits associated with sexual excess or indulgence, and any ailment associated with those habits, procuring miscarriage, and promotion of sexual virility in men or sexual desire in women. It will also be illegal to publish a document containing an intimation that any person is prepared to treat by correspondence any of these. So far the prohibition is quite general. But the following exceptions are made: "Holding out" will be permitted in the following circumstances: (1) by a physician or dentist in the exercise of his profession; (2) if it is directed to physicians, dentists, nurses, pharmacists, hospitals and persons engaged in the supply of medicines or appliances; (3) in technical publications; (4) in connection with patent applications; (5) to a patient for whom the medicine or appliance has been ordered by a physician or dentist. Certain advertisements of articles of diet which would otherwise be illegal will be permitted. But the claim must be no more than that as an article of diet the article is effective in preventing or in exercising a salutary influence (but not curing) the ailments mentioned.

Invitations to correspond with a view to diagnosis or treatment may not be issued by the proprietor or distributor of a medicine. There is a saving clause for a person who has a religious belief in the effectiveness of some means other than medicines or appliances. He may hold out this means as effective, but for this defense he must show the court that he is acting in accordance with the principle and practice of a religious body comprising a substantial number of persons who hold that belief. This exemption is designed to cover "faith healing" and treatment by prayer.

#### English Universities Decline to Attend the Celebrations of the University of Heidelberg

The British universities and learned societies have received invitations to attend the celebration of the University of Heidelberg and to present congratulations. The result is a long correspondence in the *Times* which was begun by the bishop of Durham. He pointed out that the supreme and universal claim of truth and the indispensability of liberty in its pursuit are postulates which govern the practice of civilized universities and asked whether these postulates are accepted by Heidelberg. The British universities are the vigilant guardians of intellectual freedom. The presentation of congratulations by their representatives at the present time would be understood as a deliberate condonation of the intolerance that has emptied the German universities of many of their most eminent teachers. From Heidelberg alone forty have been expelled, including Prof. Hans Sachs, the eminent serologist. In the correspondence that followed, the views of the bishop were endorsed by leading men. Sir Gowland Hopkins, professor of biochemistry at Cambridge,

wrote that three years ago all learned institutions in this country would have rejoiced in proclaiming the record of Heidelberg. But they were now asked to give the appearance of approval to the disastrous changes that have done so much to destroy academic freedom. The unusual choice of a term which corresponded to a half centenary was significant. Sir Ernest Graham Little (dermatologist and member of parliament for London University) said that "the open door" which was distinctive of London University was flouted and therefore it was unthinkable that a representative would be sent.

In the course of the correspondence it was pointed out that 1,300 professors and lecturers have been expelled from the German universities as a result of racial, religious or political persecution. Of these, 700 have left Germany and 600 have been placed in permanent or temporary posts where they can continue their work, thanks to an extraordinary manifestation of academic solidarity. The Academic Assistance Council of England has placed 200 in the British Empire. It would be strange if those who in the cause of academic freedom have come to the aid of these exiles of persecution should join in any congratulations, especially as the celebrations at an unusual time seem to be a political move—the thinly disguised aim to suggest the approval by the outer world of the Nazi rule. The defense was made that the persecution is not the work of the university but is imposed on it by the government. To this the answer has been made that under these circumstances the proper thing to do is to send Heidelberg a letter of condolence.

So far the official decisions of three universities are announced. The senate of the University of Birmingham has unanimously declined the invitation of Heidelberg University. The vice-chancellor of the University of Cambridge has informed the rector of Heidelberg that the council of the senate regrets that it is not able to propose to the university the acceptance of the invitation to participate in the celebration and has conveyed to him the council's sense of the eminent services which Heidelberg University has rendered to science and letters in the course of its long history. The University of Oxford has also declined to send a representative but will present an address in Latin.

#### Kept Alive for Four Years by Artificial Respiration

A man has died at Chiddingfold, Sussex, who was kept alive for four years by artificial respiration. In 1931 he found that he had to help his respiration by pressing on his chest. His trouble so increased that in June 1932 artificial respiration had to be performed day and night by relays of relatives and friends. In September 1933 Sir William Bragg, the physicist, who was a friend of the family, devised an apparatus in which two football bladders were connected by a wide rubber tube. One was bandaged tightly to the chest and the other was placed between two hinged boards, so that it could be worked by the feet like a bellows. This worked well. Later, at the request of Sir William Bragg, a hydraulic apparatus, to be worked off the water supply, was designed by a London scientific instrument maker. This was used up to the time of death. (THE JOURNAL, May 26, 1934, p. 1766)

#### Damages for Injuring the Sciatic Nerve

An appeal was made to the Judicial Committee of the Privy Council against a judgment of the Supreme Court of Trinidad awarding damages of \$4,300 to a man for the negligent treatment of a physician. It was claimed that the latter unskillfully treated him for malaria by inserting a hypodermic needle into the sciatic nerve when injecting quinine into the buttock or alternatively, by injecting so near the sciatic nerve as to injure it. The patient alleged that as soon as he got off the operating table he walked with a dropped right foot as a result of the injection and that the disability still continued (over three years later). In delivering judgment Lord Alness said that the trial

question concerned where the injection was made. Admittedly there was an area in the buttock within which such an injection might be safely administered. When the injection was administered to the respondent he felt a tingling sensation but nothing which he described as pain. Foot drop immediately followed. It was a fair inference, as the trial judge said, that the injection contributed to, if it did not cause, the foot drop. The appellant's theory, on the other hand, was that the respondent was suffering before the injection from latent alcoholic neuritis and that the alcoholic toxins in his system were lit up and precipitated by the shock of the injection. This theory was supported by three physicians, but one of them never saw the respondent and the other two saw him for the first time a week before the trial. The skill and experience of the appellant was certified by the trial judge. But one knew from experience in life that "familiarity breeds contempt" and that an ordinary practice was sometimes lacking in the constant care which the circumstances demanded. Moreover the respondent's theory offered a simple and convincing explanation of his plight, while the appellant's was speculative and difficult. The appellant did not treat the respondent for alcoholic neuritis, though he was addicted to spasmodic "sprees." None of the physicians who gave evidence for the appellant had experience of latent alcoholic neuritis precipitated by shock, and such a happening was admittedly rare. There was no evidence that the respondent suffered from latent alcoholic neuritis. The appeal was dismissed.

#### Acute Nephritis Following Injections of Staphylococcus Anatoxin

At the February 28 meeting of the Societe medicale des hopitaux, Tzanck reported excellent results following the use of Ramon's staphylococcus anatoxin in the treatment of superficial infections, such as furuncles, due to *Staphylococcus aureus*. At the same meeting a death due to hypersensitization to the anatoxin was reported by Duvoir. At the March 13 meeting Tzanck reported a case in which an acute nephritis appeared immediately after four injections of anatoxin had been given. A woman, aged 43, had suffered from furunculosis during the preceding three years. An intradermoreaction with the anatoxin presented a positive reaction of moderate degree. Four injections the first of 0.25 cc and the others of 0.5 cc, were given at weekly intervals. The furuncles disappeared and the patient was considered as being cured after the fourth injection. Fifteen days later the patient complained of edema around both ankles and a recurrence of furuncles in the region of the neck. Two days later a generalized edema appeared. The blood urea was 30 mg per hundred cubic centimeters and the urine contained hyaline casts and much albumin. Following the use of a salt-free diet the edema disappeared and the albumin was greatly decreased. There was a history of the presence of albuminuria during two pregnancies but no further evidence of renal disease for ten years prior to the use of the anatoxin.

In all probability, as Ramon Debre and their co-workers have pointed out, a specific allergy existed toward the staphylococcus toxin as the result of the chronic furunculosis. Tzanck has observed in ninety patients treated with the anatoxin that the reactions are more marked when the infection is of long duration. The reactions therefore are a question of individual tolerance. He believed that the anatoxin should be used only in cases of furunculosis that are very resistant to other methods of treatment and in axillary adenitis, sycoes and carbuncles. One ought to watch for reactions in patients who have had urticaria, in patients with asthma and in those who have had evidences of a nephritis at some preceding period.

#### Osteomyelitis of Jaw Treated with Staphylococcus Anatoxin

At the March 13 meeting a case of acute osteomyelitis of the upper jaw treated by operation and the anatoxin was reported by Bloch and his associates. The child was 7 months of age and presented on admission the clinical signs of a severe septicemia accompanied by local evidence of a maxillary sinusitis. The blood culture was positive for *Staphylococcus aureus*. The same organism was found in the pus of the infected sinus. The day following the operation 0.2 cc of the anatoxin was given and a second dose five days later. Immediately after the latter, the infant's general condition improved rapidly and the blood culture was negative. Recovery was uneventful. A total of 2.85 cc of the anatoxin was injected and one was able to note a progressive increase in the anitoxin content of the blood. The mortality of such cases in the past has varied from 30 to 50 per cent.

#### Study of Postoperative Pulmonary Complications

The pathogenesis of postoperative pulmonary complications is still being discussed by Professor Duval, surgeon, in collaboration with Professor Binet, physiologist, who submitted their first report at the February 12 meeting of the Academie de chirurgie. The working hypothesis employed by these investigators was that postoperative pulmonary complications were due to the toxic effects of polypeptides having their origin in the field of operation. The experiments were divided into two series, in the first of which dogs were sensitized as a preliminary measure and in the second of which the dogs were not subjected to any such preparation. The sensitizing injections were given subcutaneously and the anaphylactic injections (secondary in group 1 and primary in group 2) were given intravenously. The polypeptides were obtained by the action of phosphotungstic acid on finely divided dog's muscle after precipitation of the peptones with trichloroacetic acid. To exclude agonal pulmonary lesions and those dependent on the method of killing the animals, this was carried out by venesection and the lungs were removed by thoracotomy while the animals were still breathing. In the first group (preliminary sensitization), an injection of 0.1 Gm of polypeptides per kilogram was given three weeks before then the animal was anesthetized with chloralose and an intravenous injection of the same dose given.

The microscopic examination of the lungs revealed pulmonary lesions of two kinds: (a) apoplexy and infarction without vascular occlusion and (b) typical pulmonary atelectasis (collapse of the lung). The lung appeared to be the only organ that was involved. This can be explained by the fact that the pulmonary circulation is the first to arrest the polypeptides and seems to be particularly sensitive to them, a local state of allergy.

Although these experiments will not explain all pulmonary complications following operation, it is evident that these are not all due to the anesthetic or to an embolic process. There are two types of lesions which follow operations in an aseptic field and under conditions of rigid asepsis, even when no general anesthetic is given. These two types are (a) the infarct and (b) the collapse type. In the former, the surgeon is too apt to accept an embolic process as an explanation, even when no source of an embolism can be found.

Duval and Binet are of the opinion that these can be best understood as of anaphylactic origin. The same is true of the atelectatic (collapse) form of pulmonary complication. Intoxication by the polypeptides of autogenous origin which are a sequel of every operation can provoke the two types of pulmonary lesions, infarct and collapse.

Gregoire, in the discussion, stated that the experiments reported by Duval and Binet rendered plausible the view that

the lesion which is termed postoperative bronchopneumonia is probably an infarct due to the migration of polypeptides from the field of operation. Gregoire had obtained experimentally with the toxin of the bacillus of gas gangrene the same experimental results (intestinal and pulmonary infarcts) as he had formerly obtained with polypeptides.

#### Physician Killed by Brother of Patient

A surgeon, Dr. Taubmann of Paris, has just shared the unfortunate lot of others like Professor Pozzi and Dr. Guinard, who were killed by patients or by relatives of the latter. Dr. Taubmann had earned the respect of his colleagues and the gratitude of a large number of patients both rich and poor. He had advised that an operation be performed. The patient, a young man, died on the table. His brother overheard a conversation during which some members of the hospital personnel criticized both the manner in which the operation was performed and the judgment of the surgeon. Without stopping to consider that such remarks were not justified, the brother called on Dr. Taubmann, whom he accused of causing his brother's death, and shot him. The medical societies will take part in the prosecution of the murderer and try to show that all reasonable skill and care were employed in the diagnosis and treatment of the case.

The lesson to be learned from the ending of what promised to be a brilliant career is that members of a hospital organization, whether associates, interns or nurses, should be most guarded in making any remarks so that they can be transmitted to relatives who attempt to judge a physician's or surgeon's acts without calm consideration of the fact that both conscience and experience have guided every step in the treatment.

#### Research on the Heredity of Inmates of Institutions

For the last year H. F. Hoffmann, professor in ordinary of psychiatry at Giessen, has pursued research studies on the heredity of some 600 juvenile delinquents of his own district (Giessen). Data concerning these delinquents cover the period from the enactment of the juvenile reform school law in 1887 to 1934. Ten thousand relatives of these juveniles have thus far been genealogically established. These data are of particular importance since the vast majority of former delinquents have today grown children of their own. (Fürsorge-Zoglingen are juvenile offenders, committed to public industrial schools in the hope that their behavior may improve under the favorable influences of such surroundings.) A study of the descendants of eighty such former delinquents has yielded accurate but as yet incomplete data. This progeny present for the most part extreme types of asocial and antisocial behavior: a minority, after temporary lapses have become socially useful and fit. One hundred and eleven juvenile delinquents of more recent times were direct descendants of the eighty original offenders. In many instances all the children of the probationer had been committed to reform schools. From the existing genealogical data there may be perceived among the probationers a growing tendency to contract marriage or illicit relations with partners of low grade type. This trend is the more prevalent in families showing accumulated cases of juvenile delinquency. Thus throughout the group studied an interlocking relationship may be recognized of socially inferior families which are distinguished in most cases by the large number of children. As might have been expected, Hoffmann found among the offspring of probationers and low grade partners numerous cases of serious asocial and antisocial behavior. Many of these descendants had criminal records. The "biologic-partner law" formulated by Stumpf in connection with similar material can be

verified throughout. The rule operates in reverse for those probationers whose offenses have been less serious and for whom favorable prognoses of return to social behavior have been made. This class of reformed inmates shows in the majority of cases an inclination to contract marriage with socially worthy partners. Their family histories too present little or no hereditary taint of natural inferiority or delinquency. The descendants of such probationers almost always show fairly stable characters and incontestable social adaptability. The present data are as yet incomplete. So far as can be seen at present, the social prognosis for a human being as well as the choice of a marriage partner stand in direct proportion to the incidence of serious character defects in his immediate family circle. Those probationers of markedly inferior stamp tend to mate with similar partners and the children of such unions tend to develop a manner of life resembling that of the parents. The same holds true, but in reverse, for the milder type delinquents. For incontestable calculation the data now available must certainly be augmented.

#### Old and New Problems in Diphtheria

The meeting of the Berlin Pediatric Society (an organization the foundation of which was recently reported) was opened with a paper by Professor Optiz, director of a children's hospital in Berlin. According to statistics for the German reich, covering the last ten years, Germany is at present riding the crest of a diphtheria wave (a fact stated in several previous letters). As the result of numerous observations it may be inferred that climatic and racial factors play no part in the situation. The incidence has shifted from infancy toward school age. The clinical picture has been modified by the almost complete disappearance of croup on the one hand and by the more frequent appearance of different and more severe types of illness on the other. Toxic diphtheria has increased in a similar manner both in Europe and in North America. The more severe form the disease takes the more severe its crippling effects. These appear in 13 per cent of mild, in 20 per cent of moderately severe and in 62.9 per cent of severe cases. Among the causes of the change in the pathologic characteristics of diphtheria cases may be mentioned the improvement in general hygienic conditions and, as an obvious factor in the disappearance of croup, more suitable nutriment for children (avoidance of overfeeding with milk). Why toxic diphtheria should be on the increase is not well understood. In many cases the initial stages of the disease are atypical, and the first important hours go by without a diagnosis being established, serotherapy is then attempted but it comes too late to be of any benefit. Constitutional predisposition to diphtheria has not been proved. Idiosyncrasies of the causative agents may possibly play a part in the genesis of the disease. The so-called grave (gravis) forms seem to preponderate in cases of toxic diphtheria. When in severe cases the disease is toxic from the beginning an unusually rapid absorption of poison or some other toxic acidity in the somatic cells must be thought of. Finally let it be pointed out that, according to the modern view, diphtheria may be reckoned as a state of general illness wherein the tonsillar changes are only secondary phenomena conditioned by the elimination of bacilli.

#### Financial Aid for Impoverished Cancer Patients

More and more frequently one hears of steps being taken to facilitate the carrying out of therapeutic measures in cancer. Recently the Anticancer Federation of the Province of Hanover decided to further the campaign against cancer by extending financial assistance to impoverished and uninsured women. The nature of the assistance is as follows: Bed and care in a qualified institution is underwritten by the organization; the cost not to exceed 150 reichsmarks per diem. It is stipulated that the beneficiaries of this subsidy shall be women especially

mothers, afflicted with mammary or abdominal cancer, whose sickness insurance (if they carry any) would not cover the entire cost. Further, the institution furnishing the treatment must assume one third of the daily cost of maintenance. Moreover, it has been possible for the organization, by the purchase of its own radium and by supplies lent it free of charge to effect a reduction of 50 per cent in the cost of radiotherapy for the sickness insurance patients and for those less well off.

## ITALY

(From Our Regular Correspondent)

Feb 15 1936

### Food Problems in Italy

A committee appointed for studying some of the feeding problems in Italy came to the conclusion that cereals are the most commonly used foods among Italians. Because certain nutritional factors are either insufficient or absent in cereals the diet should have some additional foods. The following criteria are advisable in buying food for the family to spend from 30 to 35 per cent of the allowance for cereals and vegetables, from 25 to 30 per cent for meat milk and eggs, from 7 to 10 per cent for sauces and condiments and from 10 to 20 per cent for fruits and potatoes.

### Malaria in Nurslings

Dr Gioseffi, in a recent lecture, spoke on malaria in nurslings in reference to an epidemic of benign malaria which he treated several years ago and which included about 944 cases of primaveral malaria of the tertian type, five cases of the quartan type and nineteen cases of the estivo autumnal type. Most of the patients were infants from 6 months to 1 year of age. In many cases the symptoms were atypical. Chills were replaced by coldness of the hands, feet and point of the nose and cyanosis of the lips. There was no fever, sweats were absent or localized to some parts of the body and the spleen did not increase in size. Many infants showed nutritional disturbances (low weight) and paleness of the skin and mucous membranes instead of the specific malarial symptoms. As paleness may be due to improper feeding, existence of a previous disease or congenital syphilis, it is important to consider the size of the spleen in evaluating the symptom. Treatment consisted in the administration of quinine tannate in chocolate drops or as an emulsion in milk. The speaker made a more detailed study of the disease in thirty seven infants of the group. *Plasmodium vivax* was found in the blood of all infants except in two cases in which parasites of the quartan type were found and one case in which parasites of the estivo-autumnal type were found. The spleen could be felt beyond the ribs from the beginning of the disease in 46 per cent of the cases. In the remaining infants splenomegaly made its appearance later, when the infants reached about 1 year of age. The repeated examination of the blood of all infants in the group for several months after discontinuation of the treatment was negative for malarial parasites. Nine infants died (24.3 per cent) from other causes than malaria at a time when malarial parasites were no longer present in the blood as proved by repeated examinations. Malarial parasites were no longer present either in the blood of eighteen infants in the remaining group or twenty-five who are living and who were frequently seen for three years after discontinuation of the treatment. No recurrences happened in infants of this group. Recurrences took place in the rest of the cases owing either to lack of cooperation of the mothers who failed in giving their babies quinine for as long as the physician advised or to a new contagion from domestic malarial foci. The protection of babies by covering their cradles with netting gave satisfactory results in preventing the contagion.

### Italian Surgeons in International Congress of Surgery

Some Italian surgeons read papers at the International Congress of Surgery, recently held in Cairo. Professor Donati, clinical surgeon of the University of Milan, spoke on surgery of the parathyroids. He emphasized the importance of the parathyroids in the metabolisms of calcium, phosphorus and magnesium on the one hand, and of the development of modern knowledge on phosphatases, parathyroid extract and vitamin D, on the other. With this knowledge the syndromes of hyperparathyroidism and dysfunction of the parathyroids have been discovered. Hyperplasia of the parathyroids, especially focal hyperplastic adenoma of Churchill's type which the speaker names *parastruma*, is a condition in which surgical treatment is indicated. Operation is rarely indicated in hypoparathyroidism because of the inconstancy of the results from the implantation of parathyroid grafts. Hyperparathyroid syndromes include not only those syndromes of the group of Recklinghausen's osteosis which represent an advanced stage of the disease but also hyperparathyroidism with either renal or digestive disturbances which is entirely independent of osteoporosis. The diagnosis of hyperparathyroidism can be made only by study of the mineral metabolism of the patient. Professor Donati said that there are certain cases of *ostitis deformans* (Paget's disease) in which the biochemical disequilibrium shown by the patient originates in changes in the parathyroid functions. The speaker's opinion on the importance of parathyroidectomy in chronic arthropathies, scleroderma, arteritis and angiospastic syndromes was reserved. He concluded that the modern work through which the syndromes of hyperparathyroidism have been known have marked at the same time the limitations of surgical treatment. Satisfactory results from ablation of the parathyroids can be expected only in cases of hyperparathyroid hyperplasia or adenoma.

Professor Chiasseroni of Rome spoke on surgery of the lumbar sympathetic. He prefers operations on the central sympathetic rather than periarterial sympathectomy. He pointed out the importance of the spastic factor in the development of disturbances of the peripheral circulation and the necessity of evaluating the efficiency of the collateral circulation. He does not favor arteriography as a diagnostic method. As to the operation he prefers ganglionectomy by the paraperitoneal route. His experience includes fifty-two ganglionectomies with six deaths. None of the patients on whom he has operated during the last two years have died. The operation was performed in thirty-five patients with grave disturbances of circulation of the extremities caused by thromboangitis or arteriosclerotic thrombosis. The speaker followed up thirty-one of these patients and found that nineteen are still cured from three to five years after the operation, four have experienced great improvement and in four the improvement was only fair and they had then a secondary amputation. Four of the six deaths corresponded to this group.

### Personal Items

Prof Luigi D'Amato, instructor in pathology in the University of Naples, has been appointed professor of clinical medicine in the university. Some of his important contributions to medicine are on disturbances of the nitrogen and fat metabolism in diabetes mellitus, changes of the pancreas in cirrhosis of the liver, the role of chronic toxic conditions in pathogenesis of atheromatous degeneration and hemoclastic reaction for the diagnosis of syphilis, tuberculosis and some other infections, the diagnostic significance of the transmission of the laryngo-tracheal murmur audible at the clavicle as a sign of presence of diseases of the mediastinum and the paradoxical phenomenon of the displacement of vertebral dulness in pleural effusion.

Prof Leonardo Diminich, instructor in clinical surgery in the University of Perugia, has been appointed professor of surgery in the University of Naples. Some of his important

contributions to medicine are on renal functions after nephrectomy and in certain diseases, plastic surgery of the ureter, cysts of the kidney, surgery of the urinary tract, changes of the liver parenchyma in acute cholecystitis, choleperitoneum, and pathology of the heart and the blood vessels. He also made important contributions to war surgery during 1915 and 1916.

### Climate and the Treatment of Pulmonary Tuberculosis

Dr Aloysio de Paula, in a recent lecture before the Faculty of Medicine of Rio de Janeiro, said that the influence of climate on the evolution of pulmonary tuberculosis has been recognized for a long time. It was believed at first that the climate favorable for the evolution of tuberculosis was that of the coasts. Lately it has been discovered that simply a change of climate, such as that experienced in cold countries, produces a beneficial and stimulative effect on the inhabitants as well as a favorable effect on pulmonary tuberculosis. Climates have been divided into two large groups: (1) stimulative climates, among which one may consider those of high altitudes and of cold countries, in which climatic changes of seasons are marked, and (2) even climates in which the climatic variations are slight. Favorable results can be obtained from an efficient treatment in pulmonary tuberculosis in any good climate. The influence that climate has on the evolution of pulmonary tuberculosis may be explained by either a general action on the organism or by a local action on the tuberculous lesions. When a tuberculous patient first reaches a high altitude he has frequently an initial aggravation which represents a focal reaction. Amrein compares this reaction to a tuberculin reaction. The climatic shock may be either useful or harmful to the tuberculous lesion. It is possible that intense climatic variations may produce a local irritation in the tuberculous foci and that the reaction may favor the evolution of certain types of pulmonary tuberculosis. The author concluded by saying that climate is a secondary factor in the treatment of pulmonary tuberculosis but may possibly be the determining factor in the cure of the patient. In Rio de Janeiro the proper treatment of the disease has resulted in cures as good as those reported from the best climatic stations in the country. The speaker advised a careful study of the different climates in Brazil in order to establish their technical, social and psychologic indications for the various types of tuberculosis.

### Elevation of Diaphragm in Pulmonary Tuberculosis

Dr A. Ibiapina, assistant in the clinical department of Professor Austregesilo, in a recently published article on the mechanism of elevation of the diaphragm in pulmonary tuberculosis and in phrenicectomy reached the following conclusions. The elastic tension of the lung is the force that causes elevation of the diaphragm. Spontaneous elevation of the diaphragm is due to an increase of the elastic function of the lung, originating in the condensation of the pulmonary lesions and, in certain cases, to the presence of either paresis or paralysis of the phrenic nerve. The greater the extension of the pulmonary lesions, the more intense the elastic tension of the pulmonary tissue of the lung and the higher the elevation of the diaphragm. High elevations of the diaphragm following phrenicectomy correspond to extensive pulmonary lesions and to intense elastic tension of the lung while slight elevations after the same operation, correspond to small pulmonary lesions and not intense elastic tension of the lung. A high elevation of the diaphragm by phrenicectomy is not sufficient in certain cases to neutralize the preexistent high elastic tension of the lung in such a manner as to cause the organ to be left in hypoten-

sion. That is why the lesions in certain cases of pulmonary tuberculosis continue active after phrenicectomy in spite of the fact that the operation results in a high elevation of the diaphragm.

### The Annual Medical Congress

The medical congress was held at Grahamstown, the old Settler City in the eastern part of the Cape Province, last October. It was well attended and was memorable for the discussion that took place on the question "Is the white race in South Africa degenerating?" One of the most instructive papers in this symposium was read by a practitioner of forty years' standing, Dr J. Jurriaanse of Ermelo, Transvaal. He pointed out that "a certain class of whites are living on a low economic level, in some places even below that of the natives. More to the point was his reminder that, by differentiating between the native and the white man on economic and health grounds, the white settler was laying up trouble for himself, a warning of which the public has not taken the least notice. The lay press, indeed, gave little publicity to a debate that told so luridly of the evils that arise from fostering one section of the population at the expense of other sections. Scientifically, the main question at issue could not be answered, for the available data do not make it possible to say whether white civilization in South Africa is dying or developing. There is no inherent reason why the white settler should not progress in certain parts of the country, but the facts are that the old families are steadily dying out and that the physique and morale of the younger generations are not what they used to be. Factors that have probably nothing whatever to do with climate or subsoil may be responsible for this alarming condition, but so far no one has been able to collate these factors.

### Treatment of Spider Poisoning

Like America, South Africa is plagued with its own special species of *Latrodectus* spiders, which annually bite folk chiefly engaged in agricultural pursuits. Recently M. H. Finlayson has published a paper summing up the recorded evidence of poisoning by the bites of *Latrodectus concinnus* and *L. indistinctus* which in this country replace *L. mactans* of America and *L. hasseltii* of Australia. The symptoms caused by their bites are in general similar to those reported in America and Australia. Severe cramp-like pain, with abdominal rigidity, cyanosis, increased reflexes and a sharp rise of temperature are almost constant features. Death is from cardiac or respiratory failure. In the treatment, potassium permanganate is used locally with atropine and morphine, salines by rectum and solution of posterior pituitary and epinephrine to combat shock. The antiserum to the venom of *L. concinnus* does not completely neutralize the venom of the other species but experiments show that the antiserum of *L. indistinctus* neutralizes both *indistinctus* and *concinnus* venom, and it appears, therefore, to be the best and most suitable weapon in the treatment of *latrodectema*.

### Deaths in the Profession

During the last few months the medical profession in South Africa has lost more than a dozen of its older members through death. Dr A. D. Ketchen, one of the oldest medical consultants, died of heart disease. Dr H. Pellissier, a newly qualified intern, succumbed to septicemia. Dr W. Stewart, a pioneering radiologist, who was both a medical man and an electrical engineer, Dr J. C. MacNeillie, an old member of the legislature, Dr Kerr Cross, a veteran missionary practitioner who had been with Gordon in the Sudan, and Dr Targett Adams, a pioneer in public health administration and bacteriology, are others whose loss is deplored.

## Marriages

MARGARET H NELSON, Madison Wis, to Mr William A Wickers of San Juancito, Honduras, Central America, January 25, at Des Moines, Iowa

GEORGE S MAHON, Nashville, Tenn, to Miss Margarette Elizabeth McCaslin of Massillon, Ala, in Franklin, Tenn, January 4

ENNETT CARLYLE MATTHEWS, Waynesboro, Va to Miss Mary Hodnett of Chatham, February 7

## Deaths

William Fletcher Knowles ☉ Brookline, Mass Harvard University Medical School, Boston, 1885, member of the American Laryngological, Rhinological and Otolological Society fellow of the American College of Surgeons at one time instructor in otology at his alma mater served during the World War consulting aural surgeon to the Massachusetts Eye and Ear Infirmary, and the Massachusetts General Hospital Boston consulting otolaryngologist to the Boston Psychopathic Hospital and the Newton (Mass) Hospital, aged 74 died February 12

Wildy Harding Graves ☉ Murray, Ky, University of the South Medical Department, Sewanee, Tenn, 1899, Hospital College of Medicine, Louisville, 1900, secretary of the Calloway County Medical Society, formerly county health officer and member of the county board of health, member of the city council on the staff of the William Mason Memorial Hospital, aged 62, died, March 9, of coronary thrombosis

Harry S Falk ☉ Erie, Pa, Medico Chirurgical College of Philadelphia, 1899, formerly coroner of Cameron County, medical director of the Louise Home Sanatorium on the staffs of the Erie Infants' Home and Hospital and St Vincent's Hospital, Erie, and the Grand View Sanatorium Oil City, aged 61, died, February 12, of coronary occlusion

John Cutting Berry, Worcester, Mass Jefferson Medical College of Philadelphia, 1871, member of the Massachusetts Medical Society and the New England Ophthalmological Society formerly a medical missionary, on the staff of the Worcester City Hospital, aged 89, died, February 8, of myocarditis and bronchopneumonia

Fletcher Greene Sanborn, Arcadia, Calif, University of California Medical Department San Francisco, 1901, member of the Hawaiian Territorial Medical Association served during the Spanish-American and World wars aged 67 died February 8, in the Hollywood Hospital, Los Angeles, of myocarditis and coronary sclerosis

Samuel R Ward, Richmond, Ill, Georgetown University School of Medicine, Washington D C 1868, member of the Illinois State Medical Society, formerly mayor health officer and member of the school board, aged 93 died January 18, as the result of a fracture of the hip received in a fall

George Richard Little, Schaghticoke N Y University and Bellevue Hospital Medical College New York 1899 for many years president of the board of education on the associate staff of the Leonard Hospital Troy aged 58 died January 18 of cerebral hemorrhage and arteriosclerosis

George Lincoln Bunnell, Shelton Conn Cornell University Medical College New York, 1900 member of the Connecticut State Medical Society, served during the World War on the staff of the Laurel Heights State Tuberculosis Sanatorium, aged 65 died, March 8, of myocarditis

Frank Horace Clapp, North Grafton Mass University of Vermont College of Medicine Burlington 1888 member of the Massachusetts Medical Society, for many years member of the school committee and board of health of North Grafton aged 74 died, February 26, of arteriosclerosis

William Clement Gibson, Jefferson Barracks Mo University of Michigan Department of Medicine and Surgery Ann Arbor 1904, on the staff of the Veterans Administration Facility aged 60 died February 20 in the Veterans Administration Facility, West Los Angeles Calif

Homer Chester Blough ☉ Bens Creek Pa University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore 1926 aged 42 on the staff of the Mercy Hospital Johnstown where he died February 22 of an accidental overdose of phenobarbital

Robert Worth Moore, Fort Worth, Texas Fort Worth School of Medicine, 1906 member of the State Medical Association of Texas at one time lecturer on osteology and embryology at his alma mater, aged 60, died, January 23, in a local hospital, of pneumonia

Charles Edward Ryder ☉ Medical Inspector, Commander U S Navy, retired, Brooklyn, Harvard University Medical School, Boston 1898 entered the navy in 1903 and retired in 1930 for physical disability, aged 61, died, January 12, of coronary disease

William James Risen, Hooker, Okla Hospital College of Medicine, Louisville Ky, 1890, member of the Oklahoma State Medical Association county superintendent of public health aged 71, died January 18, in Liberal, Kan, of heart disease and nephritis

Herman Berg Campbell ☉ Newark N J, University of Pennsylvania Department of Medicine Philadelphia 1902, on the staffs of St Michael's Hospital, Newark, and the Orange (N J) Memorial Hospital, aged 57, died, February 5, of pneumonia

John Cohen ☉ New York, Harvard University Medical School Boston, 1924 served during the World War, aged 45 on the staffs of the Beekman Street Hospital, Montefiore Hospital and the Mount Sinai Hospital, where he died, January 24

Leonard Jarvis ☉ Claremont, N H, Harvard University Medical School, Boston, 1882, past president of the Sullivan County Medical Society on the staff of the Claremont General Hospital, aged 83, died, January 28, of cerebral hemorrhage

Charles Theodore Stovall, Vienna, Ga, Atlanta Medical College 1879, formerly mayor of Vienna and postmaster aged 78, died, January 22 in a hospital at Macon, as the result of burns received when his bed caught fire from a warming pad

Ida E Blackburn, Greensburg, Pa, Woman's Medical College of Pennsylvania Philadelphia, 1895, formerly president of the school board, for many years on the staff of the Westmoreland Hospital, aged 73, died, February 21, of heart disease

Joseph Benjamin Elliott ☉ Falkville Ala, University of Alabama Medical Department, Mobile, 1905, formerly secretary of the Morgan County Medical Society, aged 55, died February 12, in a hospital at Decatur, of pneumonia

Frederick Warder Townsend, Pacific Palisades, Calif Ohio Medical University Columbus, 1895, veteran of the Spanish-American and World wars aged 63 died, January 22 in St Luke's Hospital, Spokane, of cerebral hemorrhage

Francis George Leonard ☉ Cleveland, Starling Ohio Medical College, Columbus, 1910, fellow of the American College of Surgeons visiting surgeon to St Luke's Hospital aged 53, died, February 6 of coronary thrombosis

Ralph Warner Ellis ☉ Worcester, Mass Harvard University Medical School, Boston, 1918 medical director of Clark University, on the staff of the City Hospital aged 44, died March 3, of wounds self inflicted with a scalpel

Samuel John Joseph Kelly, Philadelphia Medico-Chirurgical College of Philadelphia 1899, for many years medical inspector for the board of health in the parochial schools aged 61, died, January 18, of cerebral embolism

Squire Raymond Boggess, Lawrenceburg Ky, University of Louisville Medical Department 1921, member of the Kentucky State Medical Association county health officer, aged 39 died, February 14, of cerebral hemorrhage

Cuvier L Clover ☉ Knox, Pa Bellevue Hospital Medical College New York 1891 past president of the Clarion County Medical Society aged 70 died February 22, in a hospital at Orlando, Fla of arteriosclerosis

Jacob Brin, St Louis, Julius-Maximilians Universität Medizinische Fakultät Würzburg Bavaria Germany, 1892 aged 69 died February 19 in the Jewish Hospital, of cerebral thrombosis and arteriosclerosis

William Milton Dill, Erie Pa University of Pennsylvania School of Medicine Philadelphia 1909 aged 56, died January 18 in St Vincent's Hospital of carcinoma of the seminal vesicle and prostate

James Mossop Cornely Madera Pa Jefferson Medical College of Philadelphia 1907, member of the Medical Society of the State of Pennsylvania, aged 58, died suddenly February 5 of heart disease

Edward Roscoe Merrill, Santa Barbara Calif Harvard University Medical School Boston 1885 member of the California Medical Association aged 77 died, recently, of endocarditis and myocarditis

## Bureau of Investigation

### "PROF" BRAGG AGAIN

#### Is Washington's Loss Miami's Gain?

For years it has been known that those sections of the country in which elderly people and invalids congregate have more than their share of quacks and faddists. For this reason southern Florida is beginning to challenge the emence of other resorts for this doubtful honor. This winter Miami has been visited by the quack who calls himself 'Professor Paul C Bragg.' Readers of *THE JOURNAL* may remember what has been published regarding Bragg, who was described as a "food faddist and sexual rejuvenator." Bragg is one of those ignoramuses with a flair for public speaking who confer on themselves ornate titles and give "free lectures," which are really come on advertisements for the books, the nostrums and the so called private courses that they have for sale.

Bragg has worked particularly along two lines—food fads and sex, two subjects that are perennially popular with the type of

tures in Washington a year ago he was charged with practicing the healing art without a license, found guilty and fined a hundred dollars. He violated the law of the District of Columbia by attempting to diagnose diseases, by prescribing a "patent medicine" of his own devising and by attempting to relieve certain diseases. He is estimated to have taken about \$7,000 out of Washington, for he charged \$20 a person for a series of six so called classes which some 350 persons attended. Observers from the office of the Commission on Licensure and from the District Medical Society attended Bragg's "classes" and obtained enough evidence to bring action against him in the police courts.

## Correspondence

### THE CORONER SYSTEM

*To the Editor*—The controversy concerning the coroner system that has been going on in England during the last two years is the inevitable protest of progress against an anachronism. Antiques belong in museums and should not continue to be parts of the government of everyday modern life. The compromise report of a royal committee appointed to correct faults in the coroner system has met with the disapproval of the British Medical Association, as was to be expected (*THE JOURNAL*, March 21, p. 1018).

The coroner system originated in the early period of Anglo-Saxon history. As the name implies, the coroner, or "crownner" was originally the personal representative of the crown in judicial procedures, but his duties came to deal particularly with investigations of deaths by violence. This country inherited the coroner system through the colonial and provincial laws that were adopted into its judicial system on the founding of the United States. Under the primitive conditions that existed before police and judicial systems were developed, the coroner and his jury fulfilled a useful purpose.

Just as scandals arising out of the character of the system and its methods gave rise to the present controversy in England so in Massachusetts in 1877 scandals caused the Massachusetts Bar Association and the Massachusetts Medical Society in joint action to investigate the system. Their studies disclosed that when a death arose from violence two basic questions had to be considered: 1. What caused the death? This could be answered only by medical investigation. 2. Who caused the death? This was a matter for the police and the courts to determine. In answering these questions the coroner was called on to straddle the functions of two professions, medicine and law. Moreover, the antiquated machinery which he governed creaking with age, operated so slowly that modern police and judicial systems made its findings ineffective and its efforts unnecessary. Under modern conditions the coroner is literally a fifth wheel on the judicial coach, and an unnecessary expense.

The Massachusetts medical examiner system (Leary, *Timothy: The Medical Examiner System*, *THE JOURNAL*, Aug. 20, 1927, p. 579; *Methods and Problems of Medical Education*, series 9 Rockefeller Foundation, New York, 1928), evolved out of the joint studies of the bar association and the medical society, abolishes the coroner, places the responsibility for determining the cause and manner of deaths by violence on the medical examiners, and refers to the police and the courts the problem of finding and prosecuting the persons committing the crimes. The system has been practiced now for fifty-eight years. It has been adopted in part in all of the New England states excepting Vermont (which has no medicolegal system) in the city of New York, and in Essex County, N. J. The medical examiner system makes for simplicity, utility and efficiency.

TIMOTHY LEARY, M.D., Boston.

Medical Examiner for Suffolk County

**MIAMI DEMANDS MORE FREE HEALTH LECTURES**  
By  
**Prof Paul C Bragg**  
Nationally Famous Health Teacher

Hundreds demand that Prof Bragg remain in Miami a few days longer and give more of his new messages of health. Therefore he has cancelled his lectures in Washington D C and will give 5 MORE FREE LECTURES

**BAPTIST AUDITORIUM**  
N E 5th St. and 1st Ave  
Mon., March 9 at 2 p.m. 8 p.m.  
Tue., Mar 10 at 2 p.m. 8 p.m.  
Friday March 15 at 8 p.m.

**5 FREE LECTURES**

**Your Opportunity to Get Health**

Over eight hundred people in the Miami area are finding Health under the BRAGG SYSTEM of eating live foods. So can You

**Don't Give Up Hope, Let Prof Bragg Show You the Way to Health**

Reproduction (reduced) of one of Bragg's advertisements in a Miami paper

intelligence that is impressed by charlatans of the Bragg type. Following the "free lectures," it has been Bragg's habit to take up collections, offer his books and 'patent medicine' for sale as well as suggest that the audience subscribe for his special classes.

Bragg seems to have found Miami a lush field this winter, but toward the end of the season he began to talk of going back north. A Miami paper however in its issue of March 8 carried a display advertisement in which it was stated that

'Miami Demands More Free Health Lectures by Professor Paul C Bragg, Nationally Famous Health Teacher.' The advertisement stated further that because of the hundreds of demands that Bragg should remain in Miami a few days longer he had 'cancelled his lectures in Washington D C, and would give five more 'free lectures'.

Bragg's cancellation of his lectures in Washington, D C, may have been due to the fact that sickers were still biting in Miami but it is quite as probable that his action was at least partly predicated on the fact that when he conducted his lec-

### "TREATING TUBERCULOSIS IN GENERAL HOSPITALS"

*To the Editor*—Your special issue on "Tuberculosis" is of special significance in my state, where the Department of Institutions has recently launched a broader program in an effort to control this disease.

A little more than three years ago, the Central Maine General Hospital cooperated with the state department of institutions in providing beds for convalescent tuberculosis patients, thus filling an unoccupied space in our hospital and making room in the sanatoriums for a large waiting list.

With the advance of surgical procedures in treatment of tuberculosis, and with the installation of such equipment as is necessary to carry on medical asepsis in tuberculosis wards and the engaging of nurses and supervisors who are properly trained, we have admitted surgical patients whose sputum has been positive.

A year ago we opened another pavilion for the treatment of fifteen surgical patients in private rooms. A tuberculosis staff has been organized having a surgeon in charge and an associate surgeon, and a physician in charge and an associate physician.

This program has brought the tuberculous patient back into the field of general medicine. As I see it there is a marked increase in the interest which the general practitioner in this community has in this unnecessary disease. Outpatient clinics have been established for diagnosis. I am sure that a number of cases have been found at a much earlier date because the members of our staff are somewhat tuberculosis conscious. The program has also made it possible to treat some private patients who would otherwise have been treated as state cases in the sanatoriums.

As I see it the trend as outlined in the Tuberculosis number 'Treating Tuberculosis in General Hospitals' is a healthy one and a much better solution for the control of this disease than state medicine ever can be. If the several states subsidized tuberculous patients in general hospitals and permitted those patients who pay a certain minimum charge to be treated as private patients by a physician of their choice the patients, the hospital and the physician would be benefited.

JOELLE C HIEBERT, M D, Lewiston, Maine  
Superintendent, Central Maine General Hospital

### STATUS OF ALLERGY TEACHING

*To the Editor*—May I be permitted to comment on an article by Dr I Harrison Tumpeer, 'Status of Allergy Teaching as indicated in Medical School Announcements' (THE JOURNAL, Aug 24 1935, p 744)?

It is fallacious to assume that because allergy is not specifically listed in the catalogue of a medical school it is therefore not taught at all or at most presented inadequately. It seems strange that this did not occur to Dr Tumpeer when sixty out of seventy-nine medical schools are so indicted.

For example in the University of Pennsylvania the teaching of allergy has had what even an allergist must consider an adequate presentation of the subject for undergraduates. There are teaching hours to second third and fourth year classes by members of the staff of the Allergy Section of the Division of Internal Medicine a section which was begun in 1920.

True our catalogue does not mention teaching hours in allergy. But neither does it mention teaching hours in numerous other subdivisions of the field of internal medicine. I assume of course, that allergy is primarily a part of the field of internal medicine an assumption that has the sanction of the Council on Medical Education and Hospitals which has so ruled in the matter of certification of specialists.

Dr Tumpeer seems to realize the weakness of his position when he concludes "A supplementary study may well be undertaken by the questionnaire method to fill in the details omitted from the catalogues." Such a study has actually been carried out by a committee of the Association for the Study of Allergy and gives quite a different picture.

That the Council on Medical Education and Hospitals or the Association of American Medical Colleges shall inform itself on the details of allergy teaching in medical schools is admitted, just as they should be familiar with the attention paid to other subdivisions of internal medicine. But that these detailed data appear in a medical school catalogue is both unnecessary and unpractical.

RICHARD A KERN M D, Philadelphia

Professor of Clinical Medicine and Chief of the Allergy  
Section of the Division of Internal Medicine Hospital  
of the University of Pennsylvania

### Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### OCCUPATIONAL HAZARD TO GASOLINE SERVICE STATION ATTENDANTS

*To the Editor*—A white man aged 29 single a gasoline service station attendant has noticed a gradual progressive impairment of vision of the left eye for the past three years. There is no associated headache or pain of any sort. For a short time about two and a half years ago he complained of diplopia but has not noticed this since. For the past two or three years he has observed at times slight difficulty in starting to urinate but this has not been a constant complaint. On several occasions he has been subject to a tic involving the muscles of the left cheek. In the past two months there has been a definite generalized weakness. The patient has worked as gasoline station attendant for the past eight years dispensing gasoline treated with tetra ethyl lead. About two months ago he was given a thorough examination. He appeared well developed and well nourished. Vision of the right eye was 20/40 and of the left eye 8/100. The eyes were entirely negative to external examination the tension pupillary reaction and extra-ocular movements being normal. Ophthalmoscopic examination showed definite pallor of the temporal sides of both disks in the area of the papillomacular bundle. This was more marked on the left than on the right side. There was no evidence of inflammatory disease in the fundi. The visual fields were essentially normal in outline for white and colors but there was a relative central color scotoma in the right eye and an absolute color scotoma in the left eye. The physical examination was essentially negative. The blood Wassermann reaction was negative. The spinal fluid had 20 cells an increased Pandey test increased protein content and a mastic colloidal gold curve and negative Wassermann reaction. The hemocytologic examination was negative throughout. The blood chemistry was normal except for the lead content of the blood which was 0.08 mg. the normal being according to standards consulted 0.05 mg. and the high level of 0.1 mg. being found in acute lead poisoning. The neurologic examination was essentially negative except for the ophthalmologic manifestations and very weak abdominal reflexes. Examination of the nose throat and accessory nasal sinuses showed a questionable infection of the ethmoidal cells although the patient had an acute cold at this time. The roentgenograms of the teeth sinuses and sella turcica were entirely negative. What conditions based on the history and examination should be included in the differential diagnosis? Does the negative blood picture exclude chronic plumbism? Can these conditions be explained on the basis of chronic plumbism? Can the spinal fluid picture be explained on the basis of chronic lead poisoning? Can the disk changes be explained by chronic plumbism? What is the most likely underlying pathologic condition in this case? If this communication is published please omit name.

M D New York

ANSWER—The ordinary operations about a filling station provide no great exposure to any of the several harmful substances that may be dispensed. Causes unrelated to work are accepted with greater probability as responsible for the condition described. However on the assumption that this condition represents an occupational disease consideration is given to four possible causes (1) tetra ethyl lead (2) methyl alcohol (3) carbon tetrachloride and (4) gasoline (naphtha benzene). The differential diagnosis here considered does not extend beyond these substances.

The possibilities of lead poisoning from casual contact with tetra-ethyl lead in gasoline have been exaggerated. The quantity of this substance per gallon of gasoline is so low as to be toxicologically insignificant. Both in the United States and England elaborate studies have been conducted among gasoline station attendants seeking to establish evidence of injury from

lead in gasoline. No such evidence has been found, and it is believed that in this case industrial exposure to lead at a filling station may be denied.

2 Methyl alcohol (methanol, wood alcohol) is widely used in some states as a preventive of freezing and is dispensed at gasoline stations. This possibly should be considered in differential diagnosis, but from the manner of dispensing wood alcohol for antifreeze purposes and the relative infrequency of this procedure, no marked attention need be extended.

3 In this day and time many gasoline stations dispense dry cleaning agents, chiefly derived from petroleum, although some blends may contain a percentage of carbon tetrachloride to render the mixture less inflammable. If actual exposure took place, carbon tetrachloride poisoning might arise in which involvement of the posterior portion of the eye might occur, such as described by Wirtschafter. Since these dry cleaning preparations are ordinarily dispensed in sealed tins, this hazard is discounted.

4 Evidence is accumulating that light petroleum derivatives are capable of producing a bizarre chronic state involving especially the central nervous system. This condition has attracted much less attention than the states arising from exposure to benzene or toluene. Explanation possibly may be found in the marked lack of uniformity in manifestation. This chronic naphtha poisoning is quite apart from the well known "naphtha jag," which closely resembles alcoholic intoxication and which condition promptly follows exposure through inhalation to any of the solvents derived from petroleum. Chronic naphtha poisoning more often than not simulates multiple sclerosis. Psychotic states may be associated. Occasionally manifestations may be limited to a single item such as perversion of taste, retrobulbar neuritis or loss of memory. Series of cases have been described by Hayhurst and by Hamilton. Retrobulbar neuritis has been described by Peters. It is impossible to present a typical case because of the lack of uniformity of symptomatology, but from the aggregate of many cases so diagnosed it may be pointed out that from time to time there arises muscular weakness with tremors, loss of reflexes, particularly the abdominal reflexes, tics, mental confusion, epileptoid seizures, loss of memory, drowsiness, changes in disposition, peripheral neuritis, and paresthesias. Jaundice is fairly common during earlier stages and so also are gastro-intestinal upsets, urinary disturbances, occasionally albuminuria and anemia. In the absence of proved marked and extended exposure, a diagnosis of chronic naphtha poisoning is unwarranted.

#### TEST FOR OCCULT BLOOD

To the Editor—There is a test for occult blood the solution for which is made of phenolphthalein some sodium salt. I think and granulated tin as a catalyzer. The material to be tested is treated with hydrogen peroxide before being layered with this solution. Will you kindly state the details of the preparation of the solutions for this test and for conducting the test? Also please state the limitations of this test. What name is usually given to it?

GRADE EDWARDS M.D. Ferozepur Punjab, India

ANSWER—The phenolphthalein test for occult blood was originally employed by Meyer (*Munchen med Wchnschr* 50 1489, 1903) and was so improved by Kastle and Amoss (*Bull* 31, Hygienic Laboratory, U S P H & M H S, 1906) that it is one of the most delicate tests for blood. Its limit of delicacy is about 1 part of blood in 8 million of water. The hemoglobin acts as an oxygen carrier, the active oxidizing agent being hydrogen peroxide.

Phenolphthalein is the reduction product of phenolphthalein, produced by the action of zinc in alkaline solution. When oxidized in alkaline solution it is converted into phenolphthalein with the formation of an intense red color. The reagent may be purchased or may be prepared as follows. Phenolphthalein is dissolved in an excess of 30 per cent sodium hydroxide solution and boiled with an excess of zinc dust until a few drops of the strongly alkaline liquid no longer gives a red color after neutralization with hydrochloric acid and sufficient alkali to alkalinize the solution. The solution is then decanted from the zinc dust, and the phenolphthalein is precipitated by the addition of hydrochloric acid. The precipitate is collected on a filter and purified by repeated crystallization from water and alcohol. This is continued until a white crystalline powder is obtained free from phenolphthalein (shown by the absence of a red color on addition of alkali). The powder is dried, contact with metallic surfaces being avoided. The powder should be kept in a tightly stoppered bottle in a dark place.

For testing for occult blood the solution is prepared as follows. Mix a slight excess of phenolphthalein, thus prepared, with 1 cc. of tenth normal sodium hydroxide solution and a few cubic centimeters of redistilled water, shake and filter. To

the filtrate add 20 cc. of tenth normal sodium hydroxide solution, 0.1 cc. of 3 per cent hydrogen peroxide solution and make up to 100 cc. To one part of an aqueous solution of a suspected stain, or of secretion or excretion to be tested, add 2 parts of the reagent and allow to stand for a few minutes. In the presence of blood a pink to red color appears, the intensity depending on the amount of blood.

This reaction is retarded by extracts of various tissues or secretions of the body. Boiling the solutions before applying the test removes most of the interfering factors. If a secretion is treated with a thick cream of aluminum hydroxide suspension, the precipitate will carry down the blood pigment and concentrate it. A small amount of this precipitate (from urine feces suspension saliva, exudates) will yield a decided red color when added to 2 cc. of the reagent. This test is especially valuable for the detection of blood in all secretions and excretions (which are boiled before the test is applied) and particularly in the examination of suspected stains for forensic purposes.

#### DISTURBANCES OF INTERNAL EAR

To the Editor—During the past two months I have had two cases which have puzzled me very much. The onset of the illness begins like a common cold. After about two hours the patients become nauseated, vomit and have severe vertigo which is subjective. This comes on if they turn in bed in both cases it has been when turning on the left side. Remaining on the right side they feel quite comfortable. There are no other symptoms referable to the ear. There is no complaint of any type except the gastric and vertigo. Physical examination of the ears, eye grounds and reflexes is all negative. The temperature is normal, the pulse but slightly elevated. All the symptoms clear up in a day or two but there may be a residual infection of the upper respiratory tract. I have treated these patients with morphine and sodium amylal. Is this condition due to a catarrhal inflammation of the vestibular or semicircular canals? I have not been able to reconcile these symptoms with a Meniere's syndrome. Has the treatment been correct? Please omit name.

M D Iowa

ANSWER—The description of the cases leads one to think that the internal ear is affected. The exact nature of the mechanism is a mystery. There are a number of explanations given. Some think that a true neuritis of the vestibular nerve may occur as the result of the toxemia of a cold. Such a condition would resemble a neuritis elsewhere and would call forth in addition the characteristic symptoms of irritation of the static labyrinth. There are others who believe that a mild labyrinthitis from a contiguous acute otitis may be present with slight exudate affecting the neuro epithelium of the labyrinth and producing characteristic signs. There are numerous other instances in which the feeling of many observers is that the condition is due to acute catarrh of the eustachian tube. This would be easy to understand because of the concomitant head cold that so often ushers in the syndrome. Catarrhal stenosis of the tube would lead to changes in the dynamics of the middle and internal ear mechanism. Catheterization of the eustachian tube in the instances is helpful. One must also consider the possibility of a drug toxemia, because many people medicate themselves at the onset of a cold with salicylates and with quinine preparations, to which the labyrinth is notoriously susceptible. The mild course of these illnesses seems proof that whatever its nature, the pathologic condition is not profound. The more severe and long standing types of vestibular disturbances to which the name Meniere's syndrome is usually attached are probably due to chronic changes, such as sclerosis, in the blood vessels supplying the internal ear.

#### MECHANISM OF AIR EMBOLISM

To the Editor—I know that air should not be introduced into the circulation in infusions transfusions or any intravenous technique but can you tell me the mechanism of an embolism and the dangers? Is it immediate as in right auricular failure? Has experimental work on large amounts tolerated been done? I have known of large amount being introduced without apparent harm. Is it a phobia unfounded that a small bubble may be fatal? I have never known of such a fatality.

CORNELL P GRAY M.D. Hanover Pa.

ANSWER—The amounts of air required to produce death in intravenous injection into animals are variable. L Welch (*Virchows Arch f path Anat* 174 454, 1904) found that 10 cc killed rabbits but that dogs could survive 250 cc. injected slowly during the course of thirty minutes. Karner (*Human Pathology*, ed 4, Philadelphia, J B Lippincott Co, 1935) reported death in the dog only after 450 cc had been injected in the course of twenty-five minutes. The variability in animals is not altogether a function of size and the results cannot be transferred quantitatively to man. The amount of air required for death of man is not known. Injected air accumulates principally in the right side of the heart and

in the pulmonary arterial system but also passes on into the systemic circulation. In the experimental animal, failure of the right side of the heart is marked. In man, injection of large quantities of air is rare. Most fatal cases are due to aspiration of air into chest veins during operations about the neck and in the chest. Here the principal factor in the cause of death is embolism into the coronary arteries (Rukstnat, George, *Experimental Air Embolism of the Coronary Arteries*, *THE JOURNAL*, Jan 3 1931, p 26) and cerebral arteries (Chase, W H, *Surg Gynec & Obst* 49 569 [Oct] 1934) rather than failure of the right side of the heart. With this consideration it is probable that relatively small quantities may be of importance. While fatalities from accidental injection of small quantities of air have not been reported it is wise to avoid the possibility, however remote, that a bubble might lodge in a coronary or cerebral artery. A minute amount of air in a syringe might be of no significance, but carelessness in this respect might ultimately result in the neglect of a column of air in the rubber tubing of an intravenous infusion apparatus.

#### DETACHMENT OF RETINA

*To the Editor*—A satisfactorily nourished single woman about 30 years of age of a myopic family, has myopia. One brother has had bilaterally detached retinas with blindness since the age of 14 years. Another brother, her sister and her father wear quite strong corrective lenses. The patient herself has had her left retina detached for a number of years with resultant complete loss of vision in the left eye. She is reasonably apprehensive of her right eye avoiding automobile rides or other recreations that would invite jars or shocks. In the good right eye an opacity of the lens has developed. Soon the cataract will be ripe enough to remove, because her remaining vision is impaired by the opaque lens. She now wears an Optica Dextra correction lens of -6.50 sphere -2 cylinder axis 15. It is known that removal of the lens in extreme myopia is beneficial to clarity of stationary focus. My question however is really that of the patient: what are the chances in skilled hands of her remaining retina becoming detached in the course of the operation thus precipitating a destruction of all sight permanently? Are there percentages available on this catastrophe or not occurring in the course of cataract extraction in myopia? If so kindly quote. Please omit name.  
M D, New York

*ANSWER*—There are no percentages available as to the frequency of occurrence of detachment of the retina after extraction of cataract in either a myopic or a normal eye. The chances of the retina becoming detached during the course of the suggested operation are slight, the greatest danger of such a detachment occurs from months to years later. The development of an opacity in a moderately myopic eye of a 30 year old patient should be investigated from the etiologic standpoint most thoroughly before the question of operation is considered. In all probability there must be a disease condition of the eye responsible for the early formation of the cataract. And the same disease condition might be a predisposing factor toward the development of a detachment. Consequently, it would appear that a thorough overhauling of that patient, both ocular and general, is in order.

#### FARASTAN OR MONO IODO CINCHOPHEN

*To the Editor*—Please give me all the information you can about a Preparation known as Farastan Mono Iodo-Cinchophen. A synthetic compound of Cinchophen and Iodine made by the Farastan Company of Ardmore Pa. I have a patient who is suffering from chronic arthritis and neuritis for whom this preparation was prescribed by another physician with considerable relief from pain. I have been afraid to use it and will not do so without assurance from you that it can be used with safety.  
M D Texas

*ANSWER*—In a report published more than five years ago the Council on Pharmacy and Chemistry declared Farastan not acceptable for inclusion in New and Nonofficial Remedies because 'it is an irrational preparation marketed with unwarranted therapeutic claims' (*THE JOURNAL* Feb 15 1930, p 484). At that time Farastan was claimed to be mono-iodo cinchophen, a new chemical complex, containing approximately 33.6 per cent of iodine. A note published three years later (*THE JOURNAL*, March 4, 1933, p 686) includes a summary of the Council's objections to Farastan, as published in its adverse report in addition to the following pertinent remark: 'There is no reason to suppose that the likelihood of producing hepatitis from Farastan is any less than that from an equivalent amount of cinchophen.'

Now the U S Department of Agriculture, in a press release dated Dec 20, 1935, calls attention to the seizure of a shipment of 'Farastan Mono-Iodo Cinchophen Compound' because 'the name was held to be false and misleading since the article consisted almost entirely of cinchophen (97%)'. This information is quite interesting in view of the manufacturer's oft repeated claim that Farastan is a 'synthetic compound of cinchophen

and iodine" which is "more valuable than the older cinchophen products" because it is "more potent therapeutically and more easily tolerated". Thus Farastan appears essentially to be cinchophen, those using cinchophen will prefer to employ products marketed under the pharmacopeial name with full knowledge of the potential dangers of this product and exploited without unwarranted and misleading claims.

#### THE INTERMEDIATE GANGLION

*To the Editor*—Howell says that the dilator fibers to the pupil pass down the spinal cord to terminate in the lower cervical region. From this point the path is continued by spinal neurons which leave the cord in the eighth cervical and the first and second thoracic spinal nerves and pass by way of the corresponding rami communicantes into the sympathetic chain at the level of the first thoracic ganglion. From this point the fibers pass upward in the cervical sympathetic without terminating until they reach the superior cervical ganglion. From this ganglion the path is continued by postganglionic fibers. De Takats (*Peripheral Vascular Diseases Arch Int Med* 56 612 [Sept] 1935) says: 'For the sympathetic denervation of the upper extremity it is necessary to cut the dorsal sympathetic trunk below the second dorsal ganglion because of a frequent communicating branch from the second ganglion to the first thoracic nerve. It also became evident that removal of the inferior cervical ganglion without the intermediate ganglion may lead to incomplete denervation or to Horner's syndrome indicating that connections are possible between the cord and the intermediate ganglion. If Horner's syndrome is due to interruption of preganglionic fibers why is it more apt to occur when the middle cervical ganglion is left intact? If by the intermediate ganglion the author means the first thoracic the same holds true. Interruption of the pathway at any point should cause Horner's syndrome. Partial preservation of the pathway would not be expected to cause the syndrome or to make it more likely to appear.'

SAMUEL L. SIMMERMAN, M.D. Philadelphia

*ANSWER*—There is a misleading, typographic error in the statement concerning the production of Horner's syndrome after sympathetic ganglionectomy. The sentence should read: "Removal of the inferior cervical ganglion without the intermediate ganglion may lead to incomplete denervation or no Horner's syndrome." The author wished to emphasize that when the intermediate ganglion is not removed there may be an absence of Horner's syndrome even though the stellate ganglion has been excised. As cervicodorsal sympathectomy is done by most surgeons through the posterior approach, this small ganglion which lies ventral and cephalic to the inferior cervical ganglion, may escape removal, and as it seems to have direct connections with the cord, the tonic influence on the eye is not or is only incompletely abolished. One of the causes of failure following cervicodorsal sympathectomy is the failure to excise this ganglion. For this reason among others, the anterior approach of Gask is preferable as this small mass of ganglion cells lies anterior to the vertebral artery.

The intermediate ganglion, according to the anatomic dissections of Cabanac (*Ann Anat path* 8 309 [March] 1931) is present in about 70 per cent of the cases. Its presence is due to a redistribution of ganglionated masses situated between the middle and inferior cervical ganglions. When present, the middle and inferior ganglions are smaller. The latter may be hidden behind the intermediate ganglion and may escape the surgeon's notice, thus again resulting in incomplete sympathetic denervation. Attention to and recognition of this structure is an important point in the technique of cervicodorsal sympathectomy.

#### CHAULMOOGRA OIL IN ARTHRITIS

*To the Editor*—I have a patient suffering from pondylitis deformans who has read in the daily newspapers of chaulmoogra oil and is anxious to use this. Please give me all the information you have in the manner of administration and dosage. The patient is 35 years of age.

CHARLES A. BALKWILL, M.D. Grafton Wis

*ANSWER*—The use of chaulmoogra oil is entirely empirical. P. A. McIlhenny first suggested this therapy and reported improvement in a series of thirty-nine cases (*Chaulmoogra Oil in the Treatment of Arthritis, New Orleans M & S J* 84 182 [Sept] 1931). G. A. Hebert made a preliminary report of a similar nature (*Treatment of Arthritis with Chaulmoogra Oil Tri-State M J* 5 1050 [Feb] 1933). Neither of these authors had any controlled series of cases and their reports will not impress those who have seen numerous therapeutic agents enthusiastically recommended and tried, only to be abandoned after more experience with them.

Chaulmoogra oil has been used for years in the treatment of leprosy and its value in this field has been favorably received. In the treatment of arthritis it has been used both orally and intramuscularly, simultaneously. One and two-thirds cubic centimeters has been recommended, taken three times daily in enteric capsules, 5 cc. of a mixture containing the oil is injected

biweekly deep into the gluteal muscles. Hebert has advised that the initial dosage be only 3 cc. The mixture consists of 0.2 Gm of benzocaine, 10 cc of olive oil and 90 cc of crude chaulmoogra oil.

There is moderate local pain after each injection and some systemic reaction occurs, characterized by leukocytosis. Several instances of abscesses in the gluteal muscles have been reported.

#### CHRONIC PANCREATITIS OR ADRENAL TUMOR

*To the Editor*—A man aged 42, a cigar salesman, whose normal weight is 160 pounds (73 kg), has been subject for the past three years to frequent attacks of gastrointestinal disturbances characterized by constipation, a sense of fullness and pain in the upper left quadrant of the abdomen. These periods are accompanied with the occurrence of rather pronounced glycosuria which promptly disappears on subsidence of the gastrointestinal symptoms. During the free periods he is apparently in normal health and his carbohydrate tolerance is quite normal while during the periods of the attacks (usually lasting from one to three days) the tolerance is low so that four drops of urine in 1 cc of reagent precipitates a heavy deposit. For the past three years he has lost 20 pounds (9 kg). Could this syndrome be due to a chronic pancreatitis with acute exacerbations? I would greatly appreciate any suggestions toward establishing a diagnosis and possible treatment. Please omit name.

M D Ohio

*ANSWER*—The description of this case is not inconsistent with the diagnosis of chronic pancreatitis with acute exacerbations mentioned in the query. An examination of the stool during or after attacks for evidence of lack of pancreatic juice or bile might be helpful.

However, it must be remembered that infection anywhere in the body may cause marked lowering of carbohydrate tolerance. Thus a diverticulitis of the colon should be considered. Roentgen examination is suggested.

If these suggestions are not productive, it might be well to visualize the region of the adrenal glands regarding the possibility of a medullary tumor.

#### CEREBRAL HEMORRHAGE WITH PARALYSIS

*To the Editor*—Please discuss the treatment of apoplectic cerebral accidents caused by edema or hemorrhage especially at the time of the accident and for the eight weeks following it. In Current Medical Literature (THE JOURNAL June 30, 1934 p. 2237) was an abstract of an article by R. Colella and G. Pizzillo on the treatment of cerebral hemorrhages and emboli by autohemotherapy. Do you know of any reason why some other foreign protein would not give as good results used in this manner as one's own blood or are there to be expected different effects from the use of different foreign proteins that are put out by different pharmaceutical houses?

H T CUMING M D Pace Miss

*ANSWER*—The accepted treatment for hemiplegia following cerebral injuries is usually cerebral exploration on the side contralateral to the paralysis. The exploration usually consists of a large decompression, following which a brain cannula is inserted into the brain at the site suggesting the location of the lesion. If a blood clot is encountered, the cortex may be incised through a silent area and the clot evacuated. Diffuse intracerebral hemorrhage with edema may be partially relieved by the cranial decompression. Dehydration accomplished by fluid limitation to 1,500 cc daily is effective treatment. Saline cathartics and intravenous dehydration by the administration daily of 1,000 cc of 20 per cent dextrose solution are likewise effective in controlling edema. There seems to be no recorded American experience with autohemotherapy in such cases.

#### TRICHOMONAS AND LEUKORRHEA

*To the Editor*—Your recently published query and minor note on leukorrhea should have mentioned trichomonas infection which of course is more productive of leukorrhea after the periods and produces no palpable pathologic changes. I should much appreciate the author of the reply referring me to the original research which proves that increased physiologic secretion due to emotional stimulation macerates the cervical mucosa and so produces a glandular hyperplasia leading to erosions and leukorrhea.

M D, Iowa

*ANSWER*—The reply to the query on leukorrhea did not mention *Trichomonas vaginalis* because the inquiry stated that repeated examination proved negative for organisms.

Our reply did not state or suggest that original research has proved that increased physiologic secretion due to emotional stimulation macerates the cervical mucosa and so produces a glandular hyperplasia leading to erosions and leukorrhea. But clinical observation has led to this deduction, and careful clinical observation of patients is often more productive than pure laboratory study. In this connection it might have been well

to mention the specific cervical changes that accompany abnormal secretion or administration of estrogenic substance, as has been emphasized by Hofbauer and others.

#### USE OF IODIZED OIL IN BRONCHOGRAPHIC WORK

*To the Editor*—How is the iodized oil used in bronchographic work prepared? 1 Is there a cheaper substitute for it? 2 Can it be prepared from some cheap oil such as cottonseed oil? 3 If so could this procedure be accomplished in a moderately well equipped laboratory?

M D, North Carolina

*ANSWER*—The original iodized oil, introduced as "Ipiodol" is 40 per cent iodine (by weight), chemically combined with the unsaturated hydrocarbon molecules of poppy-seed oil. Its exact method of manufacture is too involved for preparation except under careful chemical control. It is remarkably free from uncombined iodine.

1 Several of the other iodized oils are cheaper than iodized poppy-seed oil. Some proprietary preparations have a lower iodine content (not more than 26 per cent). If a preparation of less iodine content is desired, iodized poppy seed oil may be diluted, in which case it may be cheaper than other products.

2 Unsaturated oils other than poppy-seed oil may be used, but cottonseed oil is unsatisfactory.

3 The preparation of iodized oil has been attempted by several physicians in hospital laboratories but we do not know of any one who has been permanently satisfied with a home made oil.

#### EFFECT OF FLUID INTAKE IN EPILEPSY

*To the Editor*—What is the current opinion as to the effect of fluid intake on the treatment for epilepsy?

BEN G. CHAPMAN, M D Cromwell, Ind
